Trademark notices

Adobe™ is a trademark of Adobe Systems Incorporated.

Microsoft® and Windows® are U.S. registered trademarks of Microsoft Corporation.

UNIX® is a registered trademark of The Open Group.

This product includes an interface of the 'zlib' general purpose compression library, which is Copyright © 1995-2002 Jean-loup Gailly and Mark Adler.

Documentation updates

The title page of this document contains the following identifying information:

- Software Version number, which indicates the software version.
- Document Release Date, which changes each time the document is updated.
- Software Release Date, which indicates the release date of this version of the software.

To check for recent software updates, go to <https://downloads.autonomy.com/productDownloads.jsp>.

To verify that you are using the most recent edition of a document, go to <https://softwaresupport.hpe.com/group/softwaresupport/search-result?doctype=online help>.

This site requires that you register for an HPE Passport and sign in. To register for an HPE Passport ID, go to <https://hpp12.passport.hpe.com/hppcf/login.do>.

You will also receive updated or new editions if you subscribe to the appropriate product support service. Contact your HPE sales representative for details.

Support

Visit the HPE Software Support Online web site at <https://softwaresupport.hpe.com>.

This web site provides contact information and details about the products, services, and support that HPE Software offers.

HPE Software online support provides customer self-solve capabilities. It provides a fast and efficient way to access interactive technical support tools needed to manage your business. As a valued support customer, you can benefit by using the support web site to:

- Search for knowledge documents of interest
- Submit and track support cases and enhancement requests
- Access product documentation
- Manage support contracts
- Look up HPE support contacts
- Review information about available services
- Enter into discussions with other software customers
- Research and register for software training

Most of the support areas require that you register as an HPE Passport user and sign in. Many also require a support contract.

To register for an HPE Passport ID, go to <https://hpp12.passport.hpe.com/hppcf/login.do>.

To find more information about access levels, go to <https://softwaresupport.hpe.com/web/softwaresupport/access-levels>.

To check for recent software updates, go to <https://downloads.autonomy.com/productDownloads.jsp>.

About this PDF version of online Help

This document is a PDF version of the online Help.

This PDF file is provided so you can easily print multiple topics or read the online Help.

Because this content was originally created to be viewed as online help in a web browser, some topics may not be formatted properly. Some interactive topics may not be present in this PDF version. Those topics can be successfully printed from within the online Help.

Chapter 1: Introduction

This section provides an overview of the File System Connector.

- [File System Connector](#) 9
- [Connector Framework Server](#) 11
- [The IDOL Platform](#) 13
- [System Architecture](#) 13
- [Related Documentation](#) 14

File System Connector

File System Connector is an IDOL connector that retrieves information from file systems on local or network machines.

The File System Connector can:

- Keep IDOL up-to-date with the information in the file system.
- Collect documents from the file system and either write them to disk or send them to IDOL.
- Insert documents into the file system.
- Delete documents from the file system.

Related Topics

- [The IDOL Platform, on page 13](#)

Supported Actions

The File System Connector (CFS) supports the following actions:

Action	Supported	Further Information
Synchronize	✓	
Synchronize (identifiers)	✓	The connector's <code>Synchronize</code> action supports the optional <code>identifiers</code> parameter, which accepts a comma-separated list of document identifiers. If you set this parameter the action synchronizes the specified documents, regardless of whether they have changed.
Synchronize Groups	✗	The <code>SynchronizeGroups</code> action is not required because <code>OmniGroupServer</code> can retrieve group information through its LDAP module.

Collect	✓	
Identifiers	✓	
Insert	✓	Insert Files into the File System, on page 48
Delete/Remove	✓	
Hold/ReleaseHold	✗	
Update	✓	Update File Metadata, on page 49
Stub	✓	
GetURI	✓	
View	✓	

Mapped Security

The File System Connector supports mapped security.

The connector can retrieve:

- NT ACLs (the connector must run on Windows).
- Netware ACLs (the connector must run on Windows).
- POSIX ACLs (the connector must run on Linux and the file system must support them).

Display Online Help

You can display the File System Connector Reference by sending an action from your web browser. The File System Connector Reference describes the actions and configuration parameters that you can use with File System Connector.

For File System Connector to display help, the help data file (`help.dat`) must be available in the installation folder.

To display help for File System Connector

1. Start File System Connector.
2. Send the following action from your web browser:

```
http://host:port/action=Help
```

where:

host is the IP address or name of the machine on which File System Connector is installed.

port is the ACI port by which you send actions to File System Connector (set by the *Port* parameter in the [Server] section of the configuration file).

For example:

```
http://12.3.4.56:9000/action=help
```

OEM Certification

File System Connector works in OEM licensed environments.

Connector Framework Server

Connector Framework Server (CFS) processes the information that is retrieved by connectors, and then indexes the information into IDOL.

A single CFS can process information from any number of connectors. For example, a CFS might process files retrieved by a File System Connector, web pages retrieved by a Web Connector, and e-mail messages retrieved by an Exchange Connector.

To use the File System Connector to index documents into IDOL Server, you must have a CFS. When you install the File System Connector, you can choose to install a CFS or point the connector to an existing CFS.

For information about how to configure and use Connector Framework Server, refer to the *Connector Framework Server Administration Guide*.

Filter Documents and Extract Subfiles

The documents that are sent by connectors to CFS contain only metadata extracted from the repository, such as the location of a file or record that the connector has retrieved. CFS uses KeyView to extract the file content and file specific metadata from over 1000 different file types, and adds this information to the documents. This allows IDOL to extract meaning from the information contained in the repository, without needing to process the information in its native format.

CFS also uses KeyView to extract and process sub-files. Sub-files are files that are contained within other files. For example, an e-mail message might contain attachments that you want to index, or a Microsoft Word document might contain embedded objects.

Manipulate and Enrich Documents

CFS provides features to manipulate and enrich documents before they are indexed into IDOL. For example, you can:

- add additional fields to a document.
- divide long documents into multiple sections.

- run tasks including Education, Optical Character Recognition, or Face Recognition, and add the information that is obtained to the document.
- run a custom Lua script to modify a document.

Index Documents

After CFS finishes processing documents, it automatically indexes them into one or more indexes. CFS can index documents into:

- **IDOL Server** (or send them to a *Distributed Index Handler*, so that they can be distributed across multiple IDOL servers).
- **Haven OnDemand**.
- **Vertica**.

Import Process

This section describes the import process for new files that are added to IDOL through CFS.

1. Connectors aggregate documents from repositories and send the files to CFS. A single CFS can process documents from multiple connectors. For example, CFS might receive HTML files from HTTP Connectors, e-mail messages from Exchange Connector, and database records from ODBC Connector.

2. CFS runs pre-import tasks. Pre-Import tasks occur before document content and file-specific metadata is extracted by KeyView.
3. KeyView filters the document content, and extracts sub-files.
4. CFS runs post-import tasks. Post-Import tasks occur after KeyView has extracted document content and file-specific metadata.
5. The data is indexed into IDOL.

The IDOL Platform

At the core of File System Connector is the *Intelligent Data Operating Layer* (IDOL).

IDOL gathers and processes unstructured, semi-structured, and structured information in any format from multiple repositories using IDOL connectors and a global relational index. It can automatically form a contextual understanding of the information in real time, linking disparate data sources together based on the concepts contained within them. For example, IDOL can automatically link concepts contained in an email message to a recorded phone conversation, that can be associated with a stock trade. This information is then imported into a format that is easily searchable, adding advanced retrieval, collaboration, and personalization to an application that integrates the technology.

For more information on IDOL, see the *IDOL Getting Started Guide*.

System Architecture

An IDOL infrastructure can include the following components:

- **Connectors.** Connectors aggregate data from repositories and send the data to CFS.
- **Connector Framework Server (CFS).** Connector Framework Server (CFS) processes and enriches the information that is retrieved by connectors.
- **IDOL Server.** IDOL stores and processes the information that is indexed into it by CFS.
- **Distributed Index Handler (DIH).** The Distributed Index Handler distributes data across multiple IDOL servers. Using multiple IDOL servers can increase the availability and scalability of the system.
- **License Server.** The License server licenses multiple products.

These components can be installed in many different configurations. The simplest installation consists of a single connector, a single CFS, and a single IDOL Server.

A more complex configuration might include more than one connector, or use a Distributed Index Handler (DIH) to index content across multiple IDOL Servers.

Related Documentation

The following documents provide further information related to File System Connector.

- *File System Connector Reference*
The *File System Connector Reference* describes the configuration parameters and actions that you can use with the File System Connector.
- *Connector Framework Server Administration Guide*

Connector Framework Server (CFS) processes documents that are retrieved by connectors. CFS then indexes the documents into IDOL Server, Haven OnDemand, or Vertica. The *Connector Framework Server Administration Guide* describes how to configure and use CFS.

- *IDOL Getting Started Guide*

The *IDOL Getting Started Guide* provides an introduction to IDOL. It describes the system architecture, how to install IDOL components, and introduces indexing and security.

- *IDOL Server Administration Guide*

The *IDOL Server Administration Guide* describes the operations that IDOL server can perform with detailed descriptions of how to set them up.

- *IDOL Document Security Administration Guide*

The *IDOL Document Security Administration Guide* describes how to protect the information that you index into IDOL Server.

- *License Server Administration Guide*

This guide describes how to use a License Server to license multiple services.

Chapter 2: Install File System Connector

This section describes how to install the File System Connector.

- [System Requirements](#)16
- [Permissions](#)16
- [Install File System Connector](#)17
- [Configure the License Server Host and Port](#)17

System Requirements

File System Connector can be installed as part of a larger system that includes an IDOL Server and an interface for the information stored in IDOL Server. To maximize performance, HPE recommends that you install IDOL Server and the connector on different machines.

For information about the minimum system requirements required to run IDOL components, including File System Connector, refer to the *IDOL Getting Started Guide*.

The connector must be installed on the machine that you want to ingest files from, or on a machine that has access to those files through standard paths.

Netware File Systems

To retrieve files from a Netware file system, the connector must be installed on a machine running Windows. You must also install the Novell client on the connector machine. This allows the connector to access the Netware server.

OmniGroupServer

To extract group information, you must also install OmniGroupServer.

Permissions

This section describes the permissions that must be granted to the connector.

Action	Permissions Required
Synchronize	The connector must be able to: <ul style="list-style-type: none">• read the entire directory structure below the folder specified by DirectoryPathCSVs.• list files so that it can find the files you want to retrieve. The user account used to run the connector must have read access for the files and

	<p>folders that you want to retrieve. CFS also requires the same permission.</p> <p>TIP: Starting the connector by running the executable file uses your user account to run the connector. Unless you have the permissions described above you might need to run the connector using a different user account. To run the connector using a different user account, log on as that user.</p> <p>On Windows platforms, the File System Connector service uses the Local System account to run the connector. To retrieve files from a network share, modify the service so that it uses an account that has the necessary permissions.</p> <p>On Windows, extracting security information requires the "Read permissions" permission.</p>
Collect	The same permissions as the synchronize action. The connector must also have write-access to the collect destination folder.
Insert	The user account used to run the connector must have write access to the path where the files are inserted.
Delete/Remove	The user account used to run the connector must have permission to delete the files.
View	<p>The user account used to run the connector must have read access for the files.</p> <p>Unless the connector communicates directly with the View server, the connector also requires access to the shared path for the IDOL View Server.</p>

Install File System Connector

The File System Connector can be installed using the IDOL Server installer.

For information about installing the File System Connector using this installer, refer to the *IDOL Getting Started Guide*.

Configure the License Server Host and Port

File System Connector is licensed through License Server. In the File System Connector configuration file, specify the information required to connect to the License Server.

To specify the license server host and port

1. Open your configuration file in a text editor.
2. In the [License] section, modify the following parameters to point to your License Server.

LicenseServerHost The host name or IP address of your License Server.

LicenseServerACIPort The ACI port of your License Server.

For example:

```
[License]  
LicenseServerHost=licenses  
LicenseServerACIPort=20000
```

3. Save and close the configuration file.

Chapter 3: Configure File System Connector

This section describes how to configure the File System Connector.

- [File System Connector Configuration File](#) 19
- [Modify Configuration Parameter Values](#) 21
- [Include an External Configuration File](#) 22
- [Encrypt Passwords](#) 25
- [Configure Client Authorization](#) 27
- [Register with a Distributed Connector](#) 28
- [Set Up Secure Communication](#) 29
- [Backup and Restore the Connector's State](#) 31
- [Validate the Configuration File](#) 32
- [Example Configuration File](#) 32

File System Connector Configuration File

You can configure the File System Connector by editing the configuration file. The configuration file is located in the connector's installation folder. You can modify the file with a text editor.

The parameters in the configuration file are divided into sections that represent connector functionality.

Some parameters can be set in more than one section of the configuration file. If a parameter is set in more than one section, the value of the parameter located in the most specific section overrides the value of the parameter defined in the other sections. For example, if a parameter can be set in "*TaskName* or *FetchTasks* or *Default*", the value in the *TaskName* section overrides the value in the *FetchTasks* section, which in turn overrides the value in the *Default* section. This means that you can set a default value for a parameter, and then override that value for specific tasks.

For information about the parameters that you can use to configure the File System Connector, refer to the *File System Connector Reference*.

Server Section

The [Server] section specifies the ACI port of the connector. It can also contain parameters that control the way the connector handles ACI requests.

Service Section

The [Service] section specifies the service port of the connector.

Actions Section

The [Actions] section contains configuration parameters that specify how the connector processes actions that are sent to the ACI port. For example, you can configure event handlers that run when an action starts, finishes, or encounters an error.

Logging Section

The [Logging] section contains configuration parameters that determine how messages are logged. You can use *log streams* to send different types of message to separate log files. The configuration file also contains a section to configure each of the log streams.

Connector Section

The [Connector] section contains parameters that control general connector behavior. For example, you can specify a schedule for the fetch tasks that you configure.

Default Section

The [Default] section is used to define default settings for configuration parameters. For example, you can specify default settings for the tasks in the [FetchTasks] section.

FetchTasks Section

The [FetchTasks] section lists the fetch tasks that you want to run. A *fetch task* is a task that retrieves data from a repository. Fetch tasks are usually run automatically by the connector, but you can also run a fetch task by sending an action to the connector's ACI port.

In this section, enter the total number of fetch tasks in the `Number` parameter and then list the tasks in consecutive order starting from 0 (zero). For example:

```
[FetchTasks]
Number=2
0=MyTask0
1=MyTask1
```

[TaskName] Section

The [TaskName] section contains configuration parameters that apply to a specific task. There must be a [TaskName] section for every task listed in the [FetchTasks] section.

Ingestion Section

The [Ingestion] section specifies where to send the data that is extracted by the connector.

You can send data to a Connector Framework Server, Haven OnDemand, or another connector. For more information about ingestion, see [Ingestion, on page 72](#).

DistributedConnector Section

The [DistributedConnector] section configures the connector to operate with the Distributed Connector. The Distributed Connector is an ACI server that distributes actions (synchronize, collect and so on) between multiple connectors.

For more information about the Distributed Connector, refer to the *Distributed Connector Administration Guide*.

ViewServer Section

The [ViewServer] section contains parameters that allow the connector's *view* action to use a View Server. If necessary, the View Server converts files to HTML so that they can be viewed in a web browser.

License Section

The [License] section contains details about the License server (the server on which your license file is located).

Document Tracking Section

The [DocumentTracking] section contains parameters that enable the tracking of documents through import and indexing processes.

Related Topics

- [Modify Configuration Parameter Values, below](#)
- [Customize Logging, on page 87](#)

Modify Configuration Parameter Values

You modify File System Connector configuration parameters by directly editing the parameters in the configuration file. When you set configuration parameter values, you must use UTF-8.

CAUTION:

You must stop and restart File System Connector for new configuration settings to take effect.

This section describes how to enter parameter values in the configuration file.

Enter Boolean Values

The following settings for Boolean parameters are interchangeable:

TRUE = true = ON = on = Y = y = 1

FALSE = false = OFF = off = N = n = 0

Enter String Values

To enter a comma-separated list of strings when one of the strings contains a comma, you can indicate the start and the end of the string with quotation marks, for example:

```
ParameterName=cat,dog,bird,"wing,beak",turtle
```

Alternatively, you can escape the comma with a backslash:

```
ParameterName=cat,dog,bird,wing\,beak,turtle
```

If any string in a comma-separated list contains quotation marks, you must put this string into quotation marks and escape each quotation mark in the string by inserting a backslash before it. For example:

```
ParameterName="<font face=\"arial\" size=\"+1\"><b>\", \"<p>
```

Here, quotation marks indicate the beginning and end of the string. All quotation marks that are contained in the string are escaped.

Include an External Configuration File

You can share configuration sections or parameters between ACI server configuration files. The following sections describe different ways to include content from an external configuration file.

You can include a configuration file in its entirety, specified configuration sections, or a single parameter.

When you include content from an external configuration file, the `GetConfig` and `ValidateConfig` actions operate on the combined configuration, after any external content is merged in.

In the procedures in the following sections, you can specify external configuration file locations by using absolute paths, relative paths, and network locations. For example:

```
../sharedconfig.cfg  
K:\sharedconfig\sharedsettings.cfg  
\\example.com\shared\idol.cfg  
file://example.com/shared/idol.cfg
```

Relative paths are relative to the primary configuration file.

NOTE:

You can use nested inclusions, for example, you can refer to a shared configuration file that references a third file. However, the external configuration files must not refer back to your original configuration file. These circular references result in an error, and File System Connector does not start.

Similarly, you cannot use any of these methods to refer to a different section in your primary configuration file.

Include the Whole External Configuration File

This method allows you to import the whole external configuration file at a specified point in your configuration file.

To include the whole external configuration file

1. Open your configuration file in a text editor.
2. Find the place in the configuration file where you want to add the external configuration file.
3. On a new line, type a left angle bracket (<), followed by the path to and name of the external configuration file, in quotation marks (""). You can use relative paths and network locations. For example:

```
< "K:\sharedconfig\sharedsettings.cfg"
```

4. Save and close the configuration file.

Include Sections of an External Configuration File

This method allows you to import one or more configuration sections from an external configuration file at a specified point in your configuration file. You can include a whole configuration section in this way, but the configuration section name in the external file must exactly match what you want to use in your file. If you want to use a configuration section from the external file with a different name, see [Merge a Section from an External Configuration File, on the next page](#).

To include sections of an external configuration file

1. Open your configuration file in a text editor.
2. Find the place in the configuration file where you want to add the external configuration file section.
3. On a new line, type a left angle bracket (<), followed by the path to and name of the external configuration file, in quotation marks (""). You can use relative paths and network locations. After the configuration file name, add the configuration section name that you want to include. For example:

```
< "K:\sharedconfig\extrasettings.cfg" [License]
```

NOTE:

You cannot include a section that already exists in your configuration file.

4. Save and close the configuration file.

Include a Parameter from an External Configuration File

This method allows you to import a parameter from an external configuration file at a specified point in your configuration file. You can include a section or a single parameter in this way, but the value in the external file must exactly match what you want to use in your file.

To include a parameter from an external configuration file

1. Open your configuration file in a text editor.
2. Find the place in the configuration file where you want to add the parameter from the external configuration file.
3. On a new line, type a left angle bracket (<), followed by the path to and name of the external configuration file, in quotation marks (""). You can use relative paths and network locations. After the configuration file name, add the name of the configuration section name that contains the parameter, followed by the parameter name. For example:

```
< "license.cfg" [License] LicenseServerHost
```

To specify a default value for the parameter, in case it does not exist in the external configuration file, specify the configuration section, parameter name, and then an equals sign (=) followed by the default value. For example:

```
< "license.cfg" [License] LicenseServerHost=localhost
```

4. Save and close the configuration file.

Merge a Section from an External Configuration File

This method allows you to include a configuration section from an external configuration file as part of your File System Connector configuration file. For example, you might want to specify a standard SSL configuration section in an external file and share it between several servers. You can use this method if the configuration section that you want to import has a different name to the one you want to use.

To merge a configuration section from an external configuration file

1. Open your configuration file in a text editor.
2. Find or create the configuration section that you want to include from an external file. For example:

```
[SSLOptions1]
```

3. After the configuration section name, type a left angle bracket (<), followed by the path to and name of the external configuration file, in quotation marks (""). You can use relative paths and network locations. For example:

```
[SSLOptions1] < "../sharedconfig/ssloptions.cfg"
```

If the configuration section name in the external configuration file does not match the name that you want to use in your configuration file, specify the section to import after the configuration file name. For example:

```
[SSLOptions1] < "../sharedconfig/ssloptions.cfg" [SharedSSLOptions]
```

In this example, File System Connector uses the values in the [SharedSSLOptions] section of the external configuration file as the values in the [SSLOptions1] section of the File System Connector configuration file.

NOTE:

You can include additional configuration parameters in the section in your file. If these parameters also exist in the imported external configuration file, File System Connector uses the values in the local configuration file. For example:

```
[SSLOptions1] < "ssloptions.cfg" [SharedSSLOptions]  
SSLCACertificatesPath=C:\IDOL\HTTPConnector\CACERTS\
```

4. Save and close the configuration file.

Encrypt Passwords

HPE recommends that you encrypt all passwords that you enter into a configuration file.

Create a Key File

A key file is required to use AES encryption.

To create a new key file

1. Open a command-line window and change directory to the File System Connector installation folder.
2. At the command line, type:

```
outpassword -x -tAES -oKeyFile=./MyKeyFile.ky
```

A new key file is created with the name MyKeyFile.ky

CAUTION:

To keep your passwords secure, you must protect the key file. Set the permissions on the key file so that only authorized users and processes can read it. File System Connector must be able to read the key file to decrypt passwords, so do not move or rename it.

Encrypt a Password

The following procedure describes how to encrypt a password.

To encrypt a password

1. Open a command-line window and change directory to the File System Connector installation folder.
2. At the command line, type:

```
autopassword -e -tEncryptionType [-oKeyFile] [-cFILE -sSECTION -pPARAMETER]  
PasswordString
```

where:

Option	Description
-t <i>EncryptionType</i>	The type of encryption to use: <ul style="list-style-type: none">• Basic• AES For example: -tAES NOTE: AES is more secure than basic encryption.
-oKeyFile	AES encryption requires a key file. This option specifies the path and file name of a key file. The key file must contain 64 hexadecimal characters. For example: -oKeyFile=./key.ky
-cFILE - sSECTION - pPARAMETER	(Optional) You can use these options to write the password directly into a configuration file. You must specify all three options. <ul style="list-style-type: none">• -c. The configuration file in which to write the encrypted password.• -s. The name of the section in the configuration file in which to write the password.• -p. The name of the parameter in which to write the encrypted password. For example: -c./Config.cfg -sMyTask -pPassword
<i>PasswordString</i>	The password to encrypt.

For example:

```
autopassword -e -tBASIC MyPassword
```

```
autopassword -e -tAES -oKeyFile=./key.ky MyPassword
```

```
autopassword -e -tAES -oKeyFile=./key.ky -c./Config.cfg -sDefault -pPassword  
MyPassword
```

The password is returned, or written to the configuration file.

Decrypt a Password

The following procedure describes how to decrypt a password.

To decrypt a password

1. Open a command-line window and change directory to the File System Connector installation folder.

2. At the command line, type:

```
outpassword -d -tEncryptionType [-oKeyFile] PasswordString
```

where:

Option	Description
-t <i>EncryptionType</i>	The type of encryption: <ul style="list-style-type: none">• Basic• AES For example: -tAES
-oKeyFile	AES encryption and decryption requires a key file. This option specifies the path and file name of the key file used to decrypt the password. For example: -oKeyFile=./key.ky
<i>PasswordString</i>	The password to decrypt.

For example:

```
outpassword -d -tBASIC 9t3M3t7awt/J8A
```

```
outpassword -d -tAES -oKeyFile=./key.ky 9t3M3t7awt/J8A
```

The password is returned in plain text.

Configure Client Authorization

You can configure File System Connector to authorize different operations for different connections.

Authorization roles define a set of operations for a set of users. You define the operations by using the `StandardRoles` configuration parameter, or by explicitly defining a list of allowed actions in the `Actions` and `ServiceActions` parameters. You define the authorized users by using a client IP address, SSL identities, and GSS principals, depending on your security and system configuration.

For more information about the available parameters, see the *File System Connector Reference*.

To configure authorization roles

1. Open your configuration file in a text editor.
2. Find the `[AuthorizationRoles]` section, or create one if it does not exist.
3. In the `[AuthorizationRoles]` section, list the user authorization roles that you want to create.
For example:

```
[AuthorizationRoles]  
0=AdminRole  
1=UserRole
```

4. Create a section for each authorization role that you listed. The section name must match the name that you set in the `[AuthorizationRoles]` list. For example:

```
[AdminRole]
```

5. In the section for each role, define the operations that you want the role to be able to perform. You can set `StandardRoles` to a list of appropriate values, or specify an explicit list of allowed actions by using `Actions`, and `ServiceActions`. For example:

```
[AdminRole]  
StandardRoles=Admin,ServiceControl,ServiceStatus
```

```
[UserRole]  
Actions=GetVersion  
ServiceActions=GetStatus
```

NOTE:

The standard roles do not overlap. If you want a particular role to be able to perform all actions, you must include all the standard roles, or ensure that the clients, SSL identities, and so on, are assigned to all relevant roles.

6. In the section for each role, define the access permissions for the role, by setting `Clients`, `SSLIdentities`, and `GSSPrincipals`, as appropriate. If an incoming connection matches one of the allowed clients, principals, or SSL identities, the user has permission to perform the operations allowed by the role. For example:

```
[AdminRole]  
StandardRoles=Admin,ServiceControl,ServiceStatus  
Clients=localhost  
SSLIdentities=admin.example.com
```

7. Save and close the configuration file.
8. Restart File System Connector for your changes to take effect.

Register with a Distributed Connector

To receive actions from a Distributed Connector, a connector must register with the Distributed Connector and join a *connector group*. A connector group is a group of similar connectors. The connectors in a group must be of the same type (for example, all HTTP Connectors), and must be able to access the same repository.

To configure a connector to register with a Distributed Connector, follow these steps. For more information about the Distributed Connector, refer to the *Distributed Connector Administration Guide*.

To register with a Distributed Connector

1. Stop the connector.
2. Open the connector's configuration file in a text editor.
3. In the `[DistributedConnector]` section, set the following parameters:

`RegisterConnector` (Required) To register with a Distributed Connector, set this parameter to `true`.

HostN	(Required) The host name or IP address of the Distributed Connector.
PortN	(Required) The ACI port of the Distributed Connector.
DataPortN	(Optional) The data port of the Distributed Connector.
ConnectorGroup	(Required) The name of the connector group to join. The value of this parameter is passed to the Distributed Connector.
ConnectorPriority	(Optional) The Distributed Connector can distribute actions to connectors based on a priority value. The lower the value assigned to ConnectorPriority, the higher the probability that an action is assigned to this connector, rather than other connectors in the same connector group.
SharedPath	(Optional) The location of a shared folder that is accessible to all of the connectors in the ConnectorGroup. This folder is used to store the connectors' datastore files, so that whichever connector in the group receives an action, it can access the information required to complete it. If you set the DataPortN parameter, the datastore file is streamed directly to the Distributed Connector, and this parameter is ignored.

4. Save and close the configuration file.
5. Start the connector.

The connector registers with the Distributed Connector. When actions are sent to the Distributed Connector for the connector group that you configured, they are forwarded to this connector or to another connector in the group.

Set Up Secure Communication

You can configure Secure Socket Layer (SSL) connections between the connector and other ACI servers.

Configure Outgoing SSL Connections

To configure the connector to send data to other components (for example Connector Framework Server) over SSL, follow these steps.

To configure outgoing SSL connections

1. Open the File System Connector configuration file in a text editor.
2. Specify the name of a section in the configuration file where the SSL settings are provided:
 - To send data to an ingestion server over SSL, set the `IngestSSLConfig` parameter in the `[Ingestion]` section. To send data from a single fetch task to an ingestion server over SSL, set `IngestSSLConfig` in a `[TaskName]` section.
 - To send data to a Distributed Connector over SSL, set the `SSLConfig` parameter in the `[DistributedConnector]` section.

- To send data to a View Server over SSL, set the `SSLConfig` parameter in the `[ViewServer]` section.

You can use the same settings for each connection. For example:

```
[Ingestion]
IngestSSLConfig=SSLOptions
```

```
[DistributedConnector]
SSLConfig=SSLOptions
```

3. Create a new section in the configuration file. The name of the section must match the name you specified in the `IngestSSLConfig` or `SSLConfig` parameter. Then specify the SSL settings to use.

```
SSLMethod      The SSL protocol to use.
SSLCertificate  (Optional) The SSL certificate to use (in PEM format).
SSLPrivateKey   (Optional) The private key for the SSL certificate (in PEM format).
```

For example:

```
[SSLOptions]
SSLMethod=TLSV1.2
SSLCertificate=host1.crt
SSLPrivateKey=host1.key
```

4. Save and close the configuration file.
5. Restart the connector.

Related Topics

- [Start and Stop the Connector, on page 35](#)

Configure Incoming SSL Connections

To configure a connector to accept data sent to its ACI port over SSL, follow these steps.

To configure an incoming SSL Connection

1. Stop the connector.
2. Open the configuration file in a text editor.
3. In the `[Server]` section set the `SSLConfig` parameter to specify the name of a section in the configuration file for the SSL settings. For example:

```
[Server]
SSLConfig=SSLOptions
```

4. Create a new section in the configuration file (the name must match the name you used in the `SSLConfig` parameter). Then, use the SSL configuration parameters to specify the details for the connection. You must set the following parameters:

```
SSLMethod      The SSL protocol to use.
```

`SSLCertificate` The SSL certificate to use (in PEM format).

`SSLPrivateKey` The private key for the SSL certificate (in PEM format).

For example:

```
[SSLOptions]
SSLMethod=TLSV1.2
SSLCertificate=host1.crt
SSLPrivateKey=host1.key
```

5. Save and close the configuration file.
6. Restart the connector.

Related Topics

- [Start and Stop the Connector, on page 35](#)

Backup and Restore the Connector's State

After configuring a connector, and while the connector is running, you can create a backup of the connector's state. In the event of a failure, you can restore the connector's state from the backup.

To create a backup, use the `backupServer` action. The `backupServer` action saves a ZIP file to a path that you specify. The backup includes:

- a copy of the `actions` folder, which stores information about actions that have been queued, are running, and have finished.
- a copy of the configuration file.
- a copy of the connector's datastore files, which contain information about the files, records, or other data that the connector has retrieved from a repository.

Backup a Connector's State

To create a backup of the connectors state

- In the address bar of your Web browser, type the following action and press **ENTER**:

```
http://host:port/action=backupServer&path=path
```

where,

host The host name or IP address of the machine where the connector is running.

port The connector's ACI port.

path The folder where you want to save the backup.

For example:

```
http://localhost:1234/action=backupServer&path=./backups
```

Restore a Connector's State

To restore a connector's state

- In the address bar of your Web browser, type the following action and press **ENTER**:

```
http://host:port/action=restoreServer&filename=filename
```

where,

host The host name or IP address of the machine where the connector is running.

port The connector's ACI port.

filename The path of the backup that you created.

For example:

```
http://localhost:1234/action=restoreServer&filename=./backups/filename.zip
```

Validate the Configuration File

You can use the `ValidateConfig` service action to check for errors in the configuration file.

NOTE:

For the `ValidateConfig` action to validate a configuration section, File System Connector must have previously read that configuration. In some cases, the configuration might be read when a task is run, rather than when the component starts up. In these cases, `ValidateConfig` reports any unread sections of the configuration file as unused.

To validate the configuration file

- Send the following action to File System Connector:

```
http://Host:ServicePort/action=ValidateConfig
```

where:

Host is the host name or IP address of the machine where File System Connector is installed.

ServicePort is the service port, as specified in the `[Service]` section of the configuration file.

Example Configuration File

```
[License]  
LicenseServerHost=licenses  
LicenseServerACIPort=20000
```

```
[Server]

Chapter 4: Start and Stop the Connector

This section describes how to start and stop the File System Connector.

- [Start the Connector](#) 35
- [Verify that File System Connector is Running](#) 36
- [Stop the Connector](#) 36

NOTE:

You must start and stop the Connector Framework Server separately from the File System Connector.

Start the Connector

After you have installed and configured a connector, you are ready to run it. Start the connector using one of the following methods.

Start the Connector on Windows

To start the connector using Windows Services

1. Open the Windows Services dialog box.
2. Select the connector service, and click **Start**.
3. Close the Windows Services dialog box.

To start the connector by running the executable

- In the connector installation directory, double-click the connector executable file.

Start the Connector on UNIX

To start the connector on a UNIX operating system, follow these steps.

To start the connector using the UNIX start script

1. Change to the installation directory.
2. Enter the following command:

```
./startconnector.sh
```
3. If you want to check the File System Connector service is running, enter the following command:

```
ps -aef | grep ConnectorInstalLName
```

This command returns the File System Connector service process ID number if the service is running.

Verify that File System Connector is Running

After starting File System Connector, you can run the following actions to verify that File System Connector is running.

- [GetStatus](#)
- [GetLicenseInfo](#)

GetStatus

You can use the `GetStatus` service action to verify the File System Connector is running. For example:

```
http://Host:ServicePort/action=GetStatus
```

NOTE:

You can send the `GetStatus` action to the ACI port instead of the service port. The `GetStatus` ACI action returns information about the File System Connector setup.

GetLicenseInfo

You can send a `GetLicenseInfo` action to File System Connector to return information about your license. This action checks whether your license is valid and returns the operations that your license includes.

Send the `GetLicenseInfo` action to the File System Connector ACI port. For example:

```
http://Host:ACIport/action=GetLicenseInfo
```

The following result indicates that your license is valid.

```
<autn:license>  
  <autn:validlicense>true</autn:validlicense>  
</autn:license>
```

As an alternative to submitting the `GetLicenseInfo` action, you can view information about your license, and about licensed and unlicensed actions, on the **License** tab in the Status section of IDOL Admin.

Stop the Connector

You must stop the connector before making any changes to the configuration file.

To stop the connector using Windows Services

1. Open the Windows Services dialog box.
2. Select the *ConnectorInstallName* service, and click **Stop**.

3. Close the Windows Services dialog box.

To stop the connector by sending an action to the service port

- Type the following command in the address bar of your Web browser, and press ENTER:

`http://host:ServicePort/action=stop`

host The IP address or host name of the machine where the connector is running.

ServicePort The connector's service port (specified in the [Service] section of the connector's configuration file).

Chapter 5: Send Actions to File System Connector

This section describes how to send actions to File System Connector.

- [Send Actions to File System Connector](#) 38
- [Asynchronous Actions](#) 38
- [Store Action Queues in an External Database](#) 40
- [Store Action Queues in Memory](#) 42
- [Use XSL Templates to Transform Action Responses](#) 43

Send Actions to File System Connector

File System Connector actions are HTTP requests, which you can send, for example, from your web browser. The general syntax of these actions is:

```
http://host:port/action=action&parameters
```

where:

host is the IP address or name of the machine where File System Connector is installed.

port is the File System Connector ACI port. The ACI port is specified by the `Port` parameter in the `[Server]` section of the File System Connector configuration file. For more information about the `Port` parameter, see the *File System Connector Reference*.

action is the name of the action you want to run.

parameters are the required and optional parameters for the action.

NOTE:

Separate individual parameters with an ampersand (&). Separate parameter names from values with an equals sign (=). You must percent-encode all parameter values.

For more information about actions, see the *File System Connector Reference*.

Asynchronous Actions

When you send an asynchronous action to File System Connector, the connector adds the task to a queue and returns a token. File System Connector performs the task when a thread becomes available. You can use the token with the `QueueInfo` action to check the status of the action and retrieve the results of the action.

Most of the features provided by the connector are available through `action=fetch`, so when you use the `QueueInfo` action, query the `fetch` action queue, for example:

```
/action=QueueInfo&QueueName=Fetch&QueueAction=GetStatus
```

Check the Status of an Asynchronous Action

To check the status of an asynchronous action, use the token that was returned by File System Connector with the `QueueInfo` action. For more information about the `QueueInfo` action, refer to the *File System Connector Reference*.

To check the status of an asynchronous action

- Send the `QueueInfo` action to File System Connector with the following parameters.

<code>QueueName</code>	The name of the action queue that you want to check.
<code>QueueAction</code>	The action to perform. Set this parameter to <code>GetStatus</code> .
<code>Token</code>	(Optional) The token that the asynchronous action returned. If you do not specify a token, File System Connector returns the status of every action in the queue.

For example:

```
/action=QueueInfo&QueueName=fetch&QueueAction=getstatus&Token=...
```

Cancel an Asynchronous Action that is Queued

To cancel an asynchronous action that is waiting in a queue, use the following procedure.

To cancel an asynchronous action that is queued

- Send the `QueueInfo` action to File System Connector with the following parameters.

<code>QueueName</code>	The name of the action queue that contains the action to cancel.
<code>QueueAction</code>	The action to perform . Set this parameter to <code>Cancel</code> .
<code>Token</code>	The token that the asynchronous action returned.

For example:

```
/action=QueueInfo&QueueName=fetch&QueueAction=Cancel&Token=...
```

Stop an Asynchronous Action that is Running

You can stop an asynchronous action at any point.

To stop an asynchronous action that is running

- Send the QueueInfo action to File System Connector with the following parameters.

QueueName	The name of the action queue that contains the action to stop.
QueueAction	The action to perform. Set this parameter to Stop .
Token	The token that the asynchronous action returned.

For example:

```
/action=QueueInfo&QueueName=fetch&QueueAction=Stop&Token=...
```

Store Action Queues in an External Database

File System Connector provides asynchronous actions. Each asynchronous action has a queue to store requests until threads become available to process them. You can configure File System Connector to store these queues either in an internal database file, or in an external database hosted on a database server.

The default configuration stores queues in an internal database. Using this type of database does not require any additional configuration.

You might want to store the action queues in an external database so that several servers can share the same queues. In this configuration, sending a request to any of the servers adds the request to the shared queue. Whenever a server is ready to start processing a new request, it takes the next request from the shared queue, runs the action, and adds the results of the action back to the shared database so that they can be retrieved by any of the servers. You can therefore distribute requests between components without configuring a Distributed Action Handler (DAH).

NOTE:

You cannot use multiple servers to process a single request. Each request is processed by one server.

NOTE:

Although you can configure several connectors to share the same action queues, the connectors do not share fetch task data. If you share action queues between several connectors and distribute synchronize actions, the connector that processes a synchronize action cannot determine which items the other connectors have retrieved. This might result in some documents being ingested several times.

Prerequisites

- Supported databases:
 - PostgreSQL 9.0 or later.
 - MySQL 5.0 or later.
- If you use PostgreSQL, you must set the PostgreSQL ODBC driver setting MaxVarChar to 0 (zero).

If you use a DSN, you can configure this parameter when you create the DSN. Otherwise, you can set the `MaxVarcharSize` parameter in the connection string.

Configure File System Connector

To configure File System Connector to use a shared action queue, follow these steps.

To store action queues in an external database

1. Stop File System Connector, if it is running.
2. Open the File System Connector configuration file.
3. Find the relevant section in the configuration file:
 - To store queues for all asynchronous actions in the external database, find the `[Actions]` section.
 - To store the queue for a single asynchronous action in the external database, find the section that configures that action.
4. Set the following configuration parameters.

`AsyncStoreLibraryDirectory` The path of the directory that contains the library to use to connect to the database. Specify either an absolute path, or a path relative to the server executable file.

`AsyncStoreLibraryName` The name of the library to use to connect to the database. You can omit the file extension. The following libraries are available:

- `postgresAsyncStoreLibrary` - for connecting to a PostgreSQL database.
- `mysqlAsyncStoreLibrary` - for connecting to a MySQL database.

`ConnectionString` The connection string to use to connect to the database. The user that you specify must have permission to create tables in the database. For example:

```
ConnectionString=DSN=my_ASYNC_QUEUE
```

or

```
ConnectionString=Driver={PostgreSQL};  
Server=10.0.0.1; Port=9876;  
Database=SharedActions; Uid=user; Pwd=password;  
MaxVarcharSize=0;
```

For example:

```
[Actions]  
AsyncStoreLibraryDirectory=acidlls  
AsyncStoreLibraryName=postgresAsyncStoreLibrary  
ConnectionString=DSN=ActionStore
```

5. If you are using the same database to store action queues for more than one type of component,

set the following parameter in the [Actions] section of the configuration file.

DatastoreSharingGroupName The group of components to share actions with. You can set this parameter to any string, but the value must be the same for each server in the group. For example, to configure several File System Connectors to share their action queues, set this parameter to the same value in every File System Connector configuration. HPE recommends setting this parameter to the name of the component.

CAUTION:

Do not configure different components (for example, two different types of connector) to share the same action queues. This will result in unexpected behavior.

For example:

```
[Actions]
...
DatastoreSharingGroupName=ComponentType
```

6. Save and close the configuration file.

When you start File System Connector it connects to the shared database.

Store Action Queues in Memory

File System Connector provides asynchronous actions. Each asynchronous action has a queue to store requests until threads become available to process them. These queues are usually stored in a datastore file or in a database hosted on a database server, but in some cases you can increase performance by storing these queues in memory.

NOTE:

Storing action queues in memory improves performance only when the server receives large numbers of actions that complete quickly. Before storing queues in memory, you should also consider the following:

- The queues (including queued actions and the results of finished actions) are lost if File System Connector stops unexpectedly, for example due to a power failure or the component being forcibly stopped. This could result in some requests being lost, and if the queues are restored to a previous state some actions could run more than once.
- Storing action queues in memory prevents multiple instances of a component being able to share the same queues.
- Storing action queues in memory increases memory use, so please ensure that the server has sufficient memory to complete actions and store the action queues.

If you stop File System Connector cleanly, File System Connector writes the action queues from memory to disk so that it can resume processing when it is next started.

To configure File System Connector to store asynchronous action queues in memory, follow these steps.

To store action queues in memory

1. Stop File System Connector, if it is running.
2. Open the File System Connector configuration file and find the [Actions] section.
3. If you have set any of the following parameters, remove them:
 - AsyncStoreLibraryDirectory
 - AsyncStoreLibraryName
 - ConnectionString
 - UseStringentDatastore
4. Set the following configuration parameters.

UseInMemoryDatastore

A Boolean value that specifies whether to keep the queues for asynchronous actions in memory. Set this parameter to TRUE.

InMemoryDatastoreBackupIntervalMins

(Optional) The time interval (in minutes) at which the action queues are written to disk. Writing the queues to disk can reduce the number of queued actions that would be lost if File System Connector stops unexpectedly, but configuring a frequent backup will increase the load on the datastore and might reduce performance.

For example:

```
[Actions]
UseInMemoryDatastore=TRUE
InMemoryDatastoreBackupIntervalMins=30
```

5. Save and close the configuration file.

When you start File System Connector, it stores action queues in memory.

Use XSL Templates to Transform Action Responses

You can transform the action responses returned by File System Connector using XSL templates. You must write your own XSL templates and save them with either an .xsl or .tmpl file extension.

After creating the templates, you must configure File System Connector to use them, and then apply them to the relevant actions.

To enable XSL transformations

1. Ensure that the autnxs1t library is located in the same directory as your configuration file. If the library is not included in your installation, you can obtain it from HPE Support.
2. Open the File System Connector configuration file in a text editor.
3. In the [Server] section, ensure that the XSLTemplates parameter is set to true.

CAUTION:

If `XSLTemplates` is set to `true` and the `autnxs1t` library is not present in the same directory as the configuration file, the server will not start.

4. (Optional) In the `[Paths]` section, set the `TemplateDirectory` parameter to the path to the directory that contains your XSL templates. The default directory is `acitemplates`.
5. Save and close the configuration file.
6. Restart File System Connector for your changes to take effect.

To apply a template to action output

- Add the following parameters to the action:

<code>Template</code>	The name of the template to use to transform the action output. Exclude the folder path and file extension.
<code>ForceTemplateRefresh</code>	(Optional) If you modified the template after the server started, set this parameter to <code>true</code> to force the ACI server to reload the template from disk rather than from the cache.

For example:

```
action=QueueInfo&QueueName=Fetch
      &QueueAction=GetStatus
      &Token=...
      &Template=myTemplate
```

In this example, File System Connector applies the XSL template `myTemplate` to the response from a `QueueInfo` action.

NOTE:

If the action returns an error response, File System Connector does not apply the XSL template.

Example XSL Templates

File System Connector includes the following sample XSL templates, in the `acitemplates` folder:

XSL Template	Description
<code>FetchIdentifiers</code>	Transforms the output from the <code>Identifiers</code> fetch action, to show what is in the repository.
<code>LuaDebug</code>	Transforms the output from the <code>LuaDebug</code> action, to assist with debugging Lua scripts.

Chapter 6: Use the Connector

This section describes how to retrieve data from a file system. You can configure the connector to retrieve files that match specific criteria. For example, you can retrieve files that match a specific file type or were modified after a specific date.

To retrieve data from a file system, run the `synchronize` fetch action. You can do this manually, or by creating a *fetch task* in the connector's configuration file. The connector runs fetch tasks automatically, based on a schedule that you define.

- [Retrieve Information from a File System](#) 45
- [Schedule Fetch Tasks](#) 46
- [Synchronize from Identifiers](#) 48
- [Insert Files into the File System](#) 48
- [Update File Metadata](#) 49
- [Reset the Connector](#) 53
- [Troubleshoot the Connector](#) 54

Retrieve Information from a File System

To automatically retrieve files from a file system, create a new fetch task by following these steps. The connector runs each fetch task automatically, based on the schedule that is configured in the configuration file.

To create a new Fetch Task

1. Stop the connector.
2. Open the configuration file in a text editor.
3. In the `[FetchTasks]` section of the configuration file, specify the number of fetch tasks using the `Number` parameter. If you are configuring the first fetch task, type `Number=1`. If one or more fetch tasks have already been configured, increase the value of the `Number` parameter by one (1). Below the `Number` parameter, specify the names of the fetch tasks, starting from zero (0). For example:

```
[FetchTasks]
Number=1
0=MyTask
```

4. Below the `[FetchTasks]` section, create a new `TaskName` section. The name of the section must match the name of the new fetch task. For example:

```
[FetchTasks]
Number=1
0=MyTask

[MyTask]
```

5. To specify the folders that the connector checks for files, set the `DirectoryPathCSVs` and `DirectoryRecursive` parameters.

`DirectoryPathCSVs` A comma-separated list of folders from which you want to retrieve files.

`DirectoryRecursive` A Boolean that specifies whether the connector retrieves files in sub-folders.

```
[MyTask]
DirectoryPathCSVs=C:\MyFiles\,D:\MyFiles
DirectoryRecursive=True
```

TIP:

Using the `DirectoryPathCSVs` parameter, you can specify paths that cause the connector to retrieve files from different types of file system (for example, NT and Netware). However, HPE recommends that you create separate fetch tasks for retrieving files from different types of file system. This ensures that Access Control Lists can be retrieved correctly.

6. (Optional) To limit the folders that the connector checks for files, you can set the `PathCrawlRegex` and `PathNoCrawlRegex` parameters. These parameters can be useful when the location specified by `DirectoryPathCSVs` contains large folder structures that you do not want to index. For information about these parameters, refer to the *File System Connector (CFS) Reference*.
7. (Optional) To limit the files that are retrieved, you can use the file selection parameters. For information about these parameters, refer to the *File System Connector (CFS) Reference*. A file is retrieved only if it matches all of the criteria that are set. For example:

```
[MyTask]
DirectoryPathCSVs=C:\MyFiles\,D:\MyFiles
DirectoryRecursive=True
DirectoryFileMatch=*.pdf,*.doc
DirectoryFileModifiedSince=2012-JUN-15 00:00:01
```

8. Save and close the configuration file. You can now start the connector.

NOTE:

The connector saves or updates a data file for each completed fetch task. If you make changes to the configuration and want to reset the connector so that it retrieves all of your data again, see [Reset the Connector, on page 53](#).

Related Topics

- [Start and Stop the Connector, on page 35](#)
- [Schedule Fetch Tasks, below](#)

Schedule Fetch Tasks

The connector automatically runs the fetch tasks that you have configured, based on the schedule in the configuration file. To modify the schedule, follow these steps.

To schedule fetch tasks

1. Stop the connector.
2. Open the connector's configuration file in a text editor.
3. Find the [Connector] section.
4. The `EnableScheduledTasks` parameter specifies whether the connector should automatically run the fetch tasks that have been configured in the [FetchTasks] section. To run the tasks, set this parameter to `true`. For example:

```
[Connector]
EnableScheduledTasks=True
```

5. In the [Connector] section, set the following parameters:

`ScheduleStartTime` The start time for the fetch task, the first time it runs after you start the connector. The connector runs subsequent synchronize cycles after the interval specified by `ScheduleRepeatSecs`.

Specify the start time in the format `H[H]:MM[:SS]`. To start running tasks as soon as the connector starts, do not set this parameter or use the value `now`.

`ScheduleRepeatSecs` The interval (in seconds) from the start of one scheduled synchronize cycle to the start of the next. If a previous synchronize cycle is still running when the interval elapses, the connector queues a maximum of one action.

`ScheduleCycles` The number of times that each fetch task is run. To run the tasks continuously until the connector is stopped, set this parameter to `-1`. To run each task only one time, set this parameter to `1`.

For example:

```
[Connector]
EnableScheduledTasks=True
ScheduleStartTime=15:00:00
ScheduleRepeatSecs=3600
ScheduleCycles=-1
```

6. (Optional) To run a specific fetch task on a different schedule, you can override these parameters in a `TaskName` section of the configuration file. For example:

```
[Connector]
EnableScheduledTasks=TRUE
ScheduleStartTime=15:00:00
ScheduleRepeatSecs=3600
ScheduleCycles=-1
```

...

```
[FetchTasks]
Number=2
```

```
0=MyTask0  
1=MyTask1  
...
```

```
[MyTask1]  
ScheduleStartTime=16:00:00  
ScheduleRepeatSecs=60  
ScheduleCycles=-1
```

In this example, `MyTask0` follows the schedule defined in the `[Connector]` section, and `MyTask1` follows the scheduled defined in the `[MyTask1]` *TaskName* section.

7. Save and close the configuration file. You can now start the connector.

Related Topics

- [Start and Stop the Connector, on page 35](#)

Synchronize from Identifiers

The connector's `synchronize` action searches a repository for document updates and sends these updates for ingestion (for example, to CFS, for indexing into IDOL Server).

You can use the `identifiers` parameter to synchronize a specific set of documents, whether they have been updated or not, and ignore other files. For example:

```
/action=fetch&fetchaction=synchronize&identifiers=<identifiers>
```

(where `<identifiers>` is a comma-separated list of identifiers that specifies the documents to synchronize).

For example, if some documents fail the ingestion process, and are indexed into an IDOL Error Server, you can use the `identifiers` parameter with the `synchronize` action to retrieve those documents again. You can retrieve a list of identifiers for the failed documents by sending a query to the IDOL Error Server. For more information about IDOL Error Server, refer to the *IDOL Error Server Technical Note*. For more information about the `synchronize` action, refer to the *File System Connector Reference*.

Insert Files into the File System

The connector's `insert fetch` action can insert files into the file system. To use the `insert` action, you must construct some XML that specifies where to add each file, and the information to insert.

To insert a file, set the `reference` to the path where you want to insert the file. Use the `file` element to specify the content to insert. There are several ways that you can do this, for example specifying the path to a file or providing the content base-64 encoded. For more information about how to specify the source file, refer to the *File System Connector Reference*.

The following example would insert a file at the location `C:\files\file.txt`. The file would contain the content "This is my file".

```
<insertXML>  
  <insert>
```

```
<reference>C:\files\file.txt</reference>
<file>
  <type>content</type>
  <content>VGhpcyBpcyBteSBmaWxl</content>
</file>
<insert_id>012345</insert_id>
</insert>
</insertXML>
```

Add this XML to the insert fetch action as the value of the `insertXML` action parameter. The XML must be URL encoded before being used in the action command. For example:

```
http://host:port/action=Fetch&FetchAction=Insert
      &ConfigSection=MyTask
      &InsertXML=[URL encoded XML]
```

For more information about using the `insert` fetch action, refer to the *File System Connector Reference*.

Update File Metadata

The connector's `update` fetch action updates the metadata of files in the file system. You can change the following metadata:

- Windows** When the connector is running on Windows and the file system is on a Windows server you can modify:
- The Access Control List (ACL)
 - File creation time
 - Last access time
 - Last change time (the last time the security or sharing settings were changed)
 - Last modification time
- UNIX/Linux**
- Last access time
 - Last modification time

To use the `update` fetch action, the connector must have permission to modify files in the file system. If you are running the connector as a service and the user running the service does not have adequate permissions, set the configuration parameters `UpdateUsername` and `UpdatePassword` in the connector's configuration file. These parameters specify the user name and password of a user account to use to perform the updates.

To use the `update` fetch action, you must construct some XML that specifies the identifiers of the files to update, and provides the new values for any metadata fields that you want to change. Use the XML as the value of the action parameter `identifiersXML`. The XML must be URL-encoded before being used in the action command. For example:

```
http://host:port/action=Fetch&FetchAction=update
      &IdentifiersXML=URL-encoded XML
```

For information about how to construct the XML, see [Construct XML to Update Access Control Lists, below](#) and [Construct XML to Update Dates, on page 52](#).

Construct XML to Update Access Control Lists

To update the Access Control Lists of files in a file system, you must construct some XML that specifies the identifiers of the files to update, and provides information about how to change the ACL.

```
<identifiersXML>
  <identifier value="...">
    <acl_update>
      ...
    </acl_update>
  </identifier>
</identifiersXML>
```

In the identifier value attribute, replace "." with the document identifier of the file that you want to update. A document identifier can be found in the AUTN_IDENTIFIER field of an indexed document.

You can update the ACLs of several files by including more than one identifier element in your XML:

```
<identifiersXML>
  <identifier value="...">
    <acl_update>
      ...
    </acl_update>
  </identifier>
  <identifier value="...">
    <acl_update>
      ...
    </acl_update>
  </identifier>
</identifiersXML>
```

The following table describes the XML elements that you can use in the acl_update element to specify how to change the ACL:

XML Element	Description	Permitted Occurrences
<break_inheritance/>	Add this element to your XML to prevent ACL settings being inherited from the parent object in the file system. If specified, this element must be the first child of acl_update.	0 or 1
<enable_inheritance/>	Add this element to your XML to inherit ACL settings from the parent object in the file system. If specified, this element must be the first child of acl_update.	0 or 1

	<p>This element accepts an optional <code>revert_acl</code> attribute that specifies whether to remove all non-inherited entries in the ACL. Set this attribute to <code>true</code> or <code>false</code> (which is the default). For example:</p> <pre><enable_inheritance revert_acl="true" /></pre>	
<pre><ace action="..."></pre>	<p>Add or remove an entry from the ACL. The <code>action</code> attribute must be specified and accepts the value <code>add</code> or <code>remove</code>.</p> <p>The following child elements must all appear exactly once:</p> <ul style="list-style-type: none"> • <code>principal</code> - the user or group whose permissions you want to modify in the ACL. You can specify a domain user name or an SID. • <code>principalType</code> - the type of principal specified by the <code>principal</code> element <ul style="list-style-type: none"> ◦ <code>DomainUser</code> ◦ <code>SID</code> • <code>level</code> - a comma-separated list of permissions to add or remove. <ul style="list-style-type: none"> ◦ <code>All</code> (equivalent to "full control") ◦ <code>Read</code> ◦ <code>Write</code> ◦ <code>Execute</code> ◦ <code>Delete</code> ◦ <code>DenyAll</code> ◦ <code>DenyRead</code> ◦ <code>DenyWrite</code> ◦ <code>DenyExecute</code> ◦ <code>DenyDelete</code> 	<p>0 or more</p>

The following example demonstrates how to change the ACL for a file:

- grant read permission to MYDOMAIN\user1
- grant read, write, execute, and delete permissions to MYDOMAIN\user2
- remove all "allow" permissions from MYDOMAIN\user3

```
<identifiersXML>
  <identifier value="...">
    <acl_update>
      <break_inheritance/>
      <ace action="add">
        <principal>MYDOMAIN\user1</principal>
        <principalType>DomainUser</principalType>
```

```
    <level>Read</level>
  </ace>
  <ace action="add">
    <principal>MYDOMAIN\user2</principal>
    <principalType>DomainUser</principalType>
    <level>Read, Write, Execute, Delete</level>
  </ace>
  <ace action="remove">
    <principal>MYDOMAIN\user3</principal>
    <principalType>DomainUser</principalType>
    <level>All</level>
  </ace>
</acl_update>
</identifier>
</identifiersXML>
```

The following example demonstrates how to change the ACL for a file, so that ACL entries are inherited from the parent object in the file system and all non-inherited entries are removed:

```
<identifiersXML>
  <identifier value="...">
    <acl_update>
      <enable_inheritance revert_acl="true"/>
    </acl_update>
  </identifier>
</identifiersXML>
```

NOTE:

When you update an ACL the file's last change time is updated to the current time (unless you provide a value for the LASTCHANGED metadata field, in which case that value is used instead). For more information about changing the last change time, see [Construct XML to Update Dates](#), below.

Construct XML to Update Dates

To use the update fetch action, you must construct some XML that specifies the identifiers of the files to update, and provides the new values for any metadata fields that you want to change:

```
<identifiersXML>
  <identifier value="...">
    <metadata name="CREATED" value="1427302848"/>
    <metadata name="LASTMODIFIED" value="1427302848"/>
    <metadata name="LASTACCESSED" value="1427302848"/>
    <metadata name="LASTCHANGED" value="1427302848"/>
  </identifier>
</identifiersXML>
```

In the identifier value attribute, replace "." with the document identifier of the item that you want to update. A document identifier can be found in the AUTN_IDENTIFIER field of an indexed document.

You can update the metadata of several files by including more than one `identifier` element in your XML:

```
<identifiersXML>
  <identifier value="...">
    <metadata name="CREATED" value="1427302848"/>
  </identifier>
  <identifier value="...">
    <metadata name="LASTMODIFIED" value="1427302848"/>
  </identifier>
</identifiersXML>
```

You can set date/time values using the following formats:

- Epoch seconds (for example 1427302848)
- YYYY-SHORTMONTH-DD HH:NN:SS (for example 2015-MAR-25 17:01:30)
- YYYY-MM-DDTHH:NN:SS (for example 2015-03-25T17:01:30)
- YYYYMMDDTHHNNSS (for example 20150325T170130)

TIP:

The connector passes the times to the operating system without any consideration of time zones.

NOTE:

The connector updates any of the fields that you specify. If you do not set a value for one of the fields, the value is not updated. The last change time is *not* updated unless you explicitly set a value for that field, even though updating the other metadata fields would usually result in the last change time being updated to the current time.

Reset the Connector

When the connector runs the `synchronize` action, it updates a datastore file that stores information about the data retrieved from the repository. The next time the connector runs the `synchronize` action, it retrieves only data that is new or has been modified. The connector can also determine whether files or records have been deleted, so that related documents can be removed from the IDOL index.

When you are configuring the connector and you make a change to the configuration, you might want to purge all information from the datastore so that the connector retrieves all of your data again.

To purge the datastore for a fetch task

- To purge the datastore for a fetch task, use the `PurgeDatastore` action. Specify the name of the task as the value of the `section` parameter, for example:

```
/action=PurgeDatastore&section=MyTask
```

In some cases you might want to delete all queued actions.

To delete the actions queue

1. Stop the connector.
2. Delete the `actions` folder. This ensures that information about incomplete and queued actions is deleted.
3. Restart the connector.

Troubleshoot the Connector

This section describes how to troubleshoot common problems that might occur when you set up the File System Connector.

Files are not retrieved

If the File System Connector does not retrieve the files that you expect, check whether the files are excluded by the configuration parameters that you have set, particularly those that accept regular expressions.

If you encounter problems with permissions, ensure you run the connector as a user who has the necessary permissions for the files that you want to retrieve. For more information about permissions, see [Permissions, on page 16](#).

NSF or PST files are not retrieved

The File System Connector can retrieve files that are read-only. However, due to limitations with the MAPI and Notes APIs, KeyView cannot process read-only `.nsf` and `.pst` files.

To resolve this issue, you can:

- remove the read-only attribute from these files (the files will appear to be modified but the data, such as e-mail messages, are not changed).
- configure CFS to copy the files to a temporary directory (the temporary copies are not read-only). To do this, set the `WorkingDirectory` parameter in the CFS configuration file.

Files are ingested repeatedly

When performing extraction from `.nsf` and `.pst` files, KeyView can change the last modified date of a file. This causes the connector to re-ingest the document on the next synchronize action. You can prevent this happening by setting the `EnableExtractionCopy` parameter to `true`. When this parameter is `true`, the connector makes a copy of the original document and KeyView performs extraction on the copy.

The connector does not retrieve all items from a Netware ACL

If the connector does not retrieve all of the security information from ACLs in a Netware file system, make sure that the connector's Windows service is run by a user who has administrative permissions on the connector machine.

Chapter 7: Mapped Security

This section describes how to set up mapped security for information that is extracted from a file system.

- Introduction 55
- Set up Mapped Security 56
- Retrieve and Index Access Control Lists 56
- Retrieve ACLs from a Netware File System 57
- Retrieve Security Group Information 58

Introduction

The mapped security architecture includes the following components:

- The file system.
- HPE File System Connector (CFS)
- HPE OmniGroupServer
- HPE IDOL server
- HPE IDOL Mapped Security plug-in
- A front-end application

Files in the file system have an Access Control List (ACL) that lists the users and groups who are permitted, and are not permitted, to view the file.

The File System Connector retrieves files from the file system and sends documents to CFS to be indexed into IDOL. The connector extracts the ACL for each item, and writes it to a document field. Each time the connector synchronizes with the repository, it extracts updated ACLs.

IDOL needs the ACL to determine whether a user can view a document that is returned as a result to a query. However, IDOL must also consider the groups that the user belongs to. A user might not be permitted to view a document, but they could be a member of a group that has permission. This means that IDOL requires the user and group information associated with the files.

OmniGroupServer extracts the security group information using LDAP, and stores it.

When a user logs on to a front-end application, the application requests the user's security information and group memberships from IDOL server. IDOL returns a token containing the information. The front-end application includes this token in all queries the user sends to IDOL.

After a user submits a query, IDOL sends the result documents and the user's security token to the Mapped Security plug-in. The Mapped Security plug-in compares the user's security information and group memberships to each document's ACL. The plug-in determines which documents the user is permitted to view and returns the results. IDOL server then sends only the documents that the user is permitted to view to the front-end application.

Set up Mapped Security

To use mapped security to protect information that was extracted from a file system by the File System Connector, set up the following components:

- IDOL server. You must set up IDOL server to process the security information contained in each document. You must also configure user security, so that IDOL sends user and group information to the front-end application when a user logs on. For information about how to set up IDOL server, refer to the *IDOL Document Security Administration Guide*.
- File System Connector. You must set up the File System Connector to include security information (Access Control Lists) in the documents that are indexed into IDOL server. The connector encrypts the ACL and adds it to a document field named `AUTONOMYMETADATA`. You must also add a field to each document that identifies the security type. For information about how to do this, see [Retrieve and Index Access Control Lists](#), below.
- OmniGroupServer. You must set up OmniGroupServer to retrieve group information. HPE recommends retrieving the group information through LDAP. For information about how to configure OmniGroupServer, see [Retrieve Security Group Information](#), on page 58.
- A front-end application for querying IDOL server.

Retrieve and Index Access Control Lists

To configure the File System Connector to retrieve and index Access Control Lists (ACLs), follow these steps.

To retrieve and index Access Control Lists

1. If the connector is running, stop the connector.
2. Open the connector's configuration file.
3. Set the `MappedSecurity` parameter to `true`.
 - To index ACLs for all fetch tasks, set this parameter in the `[FetchTasks]` section.
 - To index ACLs for a single fetch task, set this parameter in the `TaskName` section for the task.

For example:

```
[FetchTasks]
MappedSecurity=True
```

4. Add a field to each document to specify the security type. To do this, create an ingest action or run a Lua script. For example:

```
[Ingestion]
IngestActions=META:SecurityType=NT
```

NOTE:

The field name and value that you specify must match the name and value you used to identify the security type in your IDOL Server configuration file.

5. Save and close the configuration file.

Retrieve ACLs from a Netware File System

This section describes how to retrieve Netware ACLs for files retrieved from a Netware file system.

Requirements

- To retrieve files from a Netware file system, the connector must be installed on a machine running Windows. You must also install the Novell client on the connector machine. This allows the connector to access the Netware server.
- Run the connector's Windows service as a user who has administrative permissions on the connector machine.
- It is possible to retrieve files from an NT file system and a Netware file system using the same fetch task. However, to retrieve Access Control Lists for the documents you must use separate fetch tasks. For example:

```
[FetchTasks]
Number=2
0=MyTask
1=Netware
MappedSecurity=True
```

```
[MyTask]
// Task for extracting files from an NT file system
```

```
DirectoryPathCSVs=\\server.domain.com\folder,\\server.domain.com\anotherfolder
```

```
[Netware]  
// Task for extracting files from Netware  
DirectoryPathCSVs=\\netware\sys\public  
NetwareServer=10.0.0.7  
NetwareUsername=CN=ADMIN.O=ORG  
NetwarePassword=password
```

- The `NetwareUsername` parameter must be set and must contain a distinguished name, for example:
`NetwareUsername=CN=ADMIN.O=ORG`
- The `DirectoryPathCSVs` configuration parameter must be configured using a full path, for example:
`DirectoryPathCSVs=\\netware\sys\public`
- To ensure that CFS has access to the files retrieved from a Netware file system, it might be necessary to make a temporary copy of the files by setting the `IngestSharedPath` parameter. For example:

```
[Ingestion]  
IngestSharedPath=\\server\IngestShared\
```

Troubleshooting

If the connector fails with the following error, this usually indicates that the value specified for the `NetwareUsername` configuration parameter is not known or is not a valid distinguished name:

```
<TASK>: Netware error 889a (NWDSLogin)  
Failed to complete <ACTION> for task '<TASK>' [<TOKEN>]: Netware initialization or  
logon failed
```

Retrieve Security Group Information

To retrieve the security groups using `OmniGroupServer`, follow these steps.

To retrieve security groups

1. Open the `OmniGroupServer` configuration file.
2. In the `[Repositories]` section, create a repository to store the groups. For example:

```
[Repositories]  
Number=1  
0=LDAP
```

3. In the new section, configure a task to extract the information from the directory using LDAP. You can use the following configuration parameters (for a complete list of configuration parameters, refer to the *OmniGroupServer Reference*).

`GroupServerLibrary` The path (including the file name) to the library file that allows the group server to access the repository. Use the LDAP group server library.

LDAPServer	The host name or IP address of the machine that hosts the LDAP directory.
LDAPPort	The port to use to access the LDAP directory.
LDAPBase	The distinguished name of the search base.
LDAPType	The type of LDAP server (for example, Microsoft Active Directory).
LDAPSecurityType	The type of security to use when communicating with the LDAP server (for example, SSL or TLS).
LDAPBindMethod	The type of authentication to use to access the LDAP directory. To log on as the same user that is running OmniGroupServer, set this parameter to NEGOTIATE.

For example:

```
[LDAP]
GroupServerLibrary=ogs_ldap.dll
LDAPServer=myLDAPserver
LDAPPort=636
LDAPBase=DC=DOMAIN,DC=COM
LDAPType=MAD
LDAPSecurityType=SSL
LDAPBindMethod=NEGOTIATE
```

4. (Optional) You can set further parameters to define the schedule for the task. You can set these parameters in the task section (to schedule only the current task), or in the [Default] section (to provide a default schedule for all OmniGroupServer tasks).

GroupServerStartTime	The time when a task starts.
GroupServerRepeatSecs	The number of seconds that elapse before the Group Server repeats a task.

For example:

```
[LDAP]
GroupServerLibrary=ogs_ldap.dll
LDAPServer=myLDAPserver
LDAPPort=636
LDAPBase=DC=DOMAIN,DC=COM
LDAPType=MAD
LDAPSecurityType=SSL
LDAPBindMethod=NEGOTIATE
GroupServerStartTime=12:00
GroupServerRepeatSecs=3600
```

5. Save and close the OmniGroupServer configuration file.

Chapter 8: Manipulate Documents

This section describes how to manipulate documents that are created by the connector and sent for ingestion.

- [Introduction](#) 60
- [Add a Field to Documents using an Ingest Action](#) 60
- [Customize Document Processing](#) 61
- [Standardize Field Names](#) 62
- [Run Lua Scripts](#) 67
- [Example Lua Scripts](#) 69

Introduction

IDOL Connectors retrieve data from repositories and create documents that are sent to Connector Framework Server, another connector, or Haven OnDemand. You might want to manipulate the documents that are created. For example, you can:

- Add or modify document fields, to change the information that is indexed into IDOL Server or Haven OnDemand.
- Add fields to a document to customize the way the document is processed by CFS.
- Convert information into another format so that it can be inserted into another repository by a connector that supports the `Insert` action.

When a connector sends documents to CFS, the documents only contain metadata extracted from the repository by the connector (for example, the location of the original files). To modify data extracted by KeyView, you must modify the documents using CFS. For information about how to manipulate documents with CFS, refer to the *Connector Framework Server Administration Guide*.

Add a Field to Documents using an Ingest Action

To add a field to all documents retrieved by a fetch task, or all documents sent for ingestion, you can use an Ingest Action.

NOTE:

To add a field only to selected documents, use a Lua script (see [Run Lua Scripts, on page 67](#)). For an example Lua script that demonstrates how to add a field to a document, see [Add a Field to a Document, on page 70](#).

To add a field to documents using an Ingest Action

1. Open the connector's configuration file.
2. Find one of the following sections in the configuration file:

- To add the field to all documents retrieved by a specific fetch task, find the [TaskName] section.
- To add a field to all documents that are sent for ingestion, find the [Ingestion] section.

NOTE:

If you set the `IngestActions` parameter in a [TaskName] section, the connector does not run any `IngestActions` set in the [Ingestion] section for documents retrieved by that task.

3. Use the `IngestActions` parameter to specify the name of the field to add, and the field value. For example, to add a field named `AUTN_NO_EXTRACT`, with the value `SET`, type:

```
IngestActions0=META:AUTN_NO_EXTRACT=SET
```

4. Save and close the configuration file.

Customize Document Processing

You can add the following fields to a document to control how the document is processed by CFS. Unless stated otherwise, you can add the fields with any value.

AUTN_FILTER_META_ONLY

Prevents KeyView extracting file content from a file. KeyView only extracts metadata and adds this information to the document.

AUTN_NO_FILTER

Prevents KeyView extracting file content and metadata from a file. You can use this field if you do not want to extract text from certain file types.

AUTN_NO_EXTRACT

Prevents KeyView extracting subfiles. You can use this field to prevent KeyView extracting the contents of ZIP archives and other container files.

AUTN_NEEDS_MEDIA_SERVER_ANALYSIS

Identifies media files (images, video, and documents such as PDF files that contain embedded images) that you want to send to Media Server for analysis, using a `MediaServerAnalysis` import task. You do not need to add this field if you are using a Lua script to run media analysis. For more information about running analysis on media, refer to the *Connector Framework Server Administration Guide*.

AUTN_NEEDS_TRANSCRIPTION

Identifies audio and video assets that you want to send to an IDOL Speech Server for speech-to-text processing, using an `IdolSpeech` import task. You do not need to add this field if you are using a Lua script to run speech-to-text. For more information about running speech-to-text on documents, refer to the *Connector Framework Server Administration Guide*.

AUTN_FORMAT_CORRECT_FOR_TRANSCRIPTION

To bypass the transcoding step of an `IdolSpeech` import task, add the field `AUTN_FORMAT_CORRECT_FOR_TRANSCRIPTION`. Documents that have this field are not sent to a Transcode Server. For more

information about the `Ido1Speech` task, refer to the *Connector Framework Server Administration Guide*.

AUTN_AUDIO_LANGUAGE

To bypass the language identification step of an `Ido1Speech` import task add the field `AUTN_AUDIO_LANGUAGE`. The value of the field must be the name of the IDOL Speech Server language pack to use for extracting speech. Documents that have this field are not sent to the IDOL Speech Server for language identification. For more information about the `Ido1Speech` task, refer to the *Connector Framework Server Administration Guide*.

Standardize Field Names

Field standardization modifies documents so that they have a consistent structure and consistent field names. You can use field standardization so that documents indexed into IDOL through different connectors use the same fields to store the same type of information.

For example, documents created by the File System Connector can have a field named `FILEOWNER`. Documents created by the Documentum Connector can have a field named `owner_name`. Both of these fields store the name of the person who owns a file. Field standardization renames the fields so that they have the same name.

Field standardization only modifies fields that are specified in a dictionary, which is defined in XML format. A standard dictionary, named `dictionary.xml`, is supplied in the installation folder of every connector. If a connector does not have any entries in the dictionary, field standardization has no effect.

Configure Field Standardization

IDOL Connectors have several configuration parameters that control field standardization. All of these are set in the `[Connector]` section of the configuration file:

- `EnableFieldNameStandardization` specifies whether to run field standardization.
- `FieldNameDictionaryPath` specifies the path of the dictionary file to use.
- `FieldNameDictionaryNode` specifies the rules to use. The default value for this parameter matches the name of the connector, and HPE recommends that you do not change it. This prevents one connector running field standardization rules that are intended for another.

To configure field standardization, use the following procedure.

NOTE:

You can also configure CFS to run field standardization. To standardize all field names, you must run field standardization from both the connector and CFS.

To enable field standardization

1. Stop the connector.
2. Open the connector's configuration file.
3. In the `[Connector]` section, set the following parameters:

<code>EnableFieldNameStandardization</code>	A Boolean value that specifies whether to enable field standardization. Set this parameter to <code>true</code> .
<code>FieldNameDictionaryPath</code>	The path to the dictionary file that contains the rules to use to standardize documents. A standard dictionary is included with the connector and is named <code>dictionary.xml</code> .

For example:

```
[Connector]
EnableFieldNameStandardization=true
FieldNameDictionaryPath=dictionary.xml
```

4. Save the configuration file and restart the connector.

Customize Field Standardization

Field standardization modifies documents so that they have a consistent structure and consistent field names. You can use field standardization so that documents indexed into IDOL through different connectors use the same fields to store the same type of information. Field standardization only modifies fields that are specified in a dictionary, which is defined in XML format. A standard dictionary, named `dictionary.xml`, is supplied in the installation folder of every connector.

In most cases you should not need to modify the standard dictionary, but you can modify it to suit your requirements or create dictionaries for different purposes. By modifying the dictionary, you can configure the connector to apply rules that modify documents before they are ingested. For example, you can move fields, delete fields, or change the format of field values.

The following examples demonstrate how to perform some operations with field standardization.

The following rule renames the field `Author` to `DOCUMENT_METADATA_AUTHOR_STRING`. This rule applies to all components that run field standardization and applies to all documents.

```
<FieldStandardization>
  <Field name="Author">
    <Move name="DOCUMENT_METADATA_AUTHOR_STRING"/>
  </Field>
</FieldStandardization>
```

The following rule demonstrates how to use the `Delete` operation. This rule instructs CFS to remove the field `KeyviewVersion` from all documents (the `Product` element with the attribute `key="ConnectorFrameWork"` ensures that this rule is run only by CFS).

```
<FieldStandardization>
  <Product key="ConnectorFrameWork">
    <Field name="KeyviewVersion">
      <Delete/>
    </Field>
  </Product>
</FieldStandardization>
```

There are several ways to select fields to process using the `Field` element.

Field element attribute	Description	Example
name	Select a field where the field name matches a fixed value.	Select the field MyField: <pre><Field name="MyField"> ... </Field></pre> Select the field Subfield, which is a subfield of MyField: <pre><Field name="MyField"> <Field name="Subfield"> ... </Field> </Field></pre>
path	Select a field where its path matches a fixed value.	Select the field Subfield, which is a subfield of MyField. <pre><Field path="MyField/Subfield"> ... </Field></pre>
nameRegex	Select all fields at the current depth where the field name matches a regular expression.	In this case the field name must begin with the word File: <pre><Field nameRegex="File.*"> ... </Field></pre>
pathRegex	Select all fields where the path of the field matches a regular expression. This operation can be inefficient because every metadata field must be checked. If possible, select the fields to process another way.	This example selects all subfields of MyField. <pre><Field pathRegex="MyField/[^/]*"> ... </Field></pre> This approach would be more efficient: <pre><Field name="MyField"> <Field nameRegex=".*"> ... </Field> </Field></pre>

You can also limit the fields that are processed based on their value, by using one of the following:

Field element attribute	Description	Example
matches	Process a field if its value matches a fixed value.	Process a field named MyField, if its value matches abc.

		<pre><Field name="MyField" matches="abc"> ... </Field></pre>
matchesRegex	Process a field if its entire value matches a regular expression.	<p>Process a field named MyField, if its value matches one or more digits.</p> <pre><Field name="MyField" matchesRegex="\d+"> ... </Field></pre>
containsRegex	Process a field if its value contains a match to a regular expression.	<p>Process a field named MyField if its value contains three consecutive digits.</p> <pre><Field name="MyField" containsRegex="\d{3}"> ... </Field></pre>

The following rule deletes every field or subfield where the name of the field or subfield begins with temp.

```
<FieldStandardization>
  <Field pathRegex="(.*\/)?temp[^\/*]">
    <Delete/>
  </Field>
</FieldStandardization>
```

The following rule instructs CFS to rename the field Author to DOCUMENT_METADATA_AUTHOR_STRING, but only when the document contains a field named DocumentType with the value 230 (the KeyView format code for a PDF file).

```
<FieldStandardization>
  <Product key="ConnectorFramework">
    <IfField name="DocumentType" matches="230"> <!-- PDF -->
      <Field name="Author">
        <Move name="DOCUMENT_METADATA_AUTHOR_STRING"/>
      </Field>
    </IfField>
  </Product>
</FieldStandardization>
```

TIP:

In this example, the IfField element is used to check the value of the DocumentType field. The IfField element does not change the current position in the document. If you used the Field element, field standardization would attempt to find an Author field that is a subfield of DocumentType, instead of finding the Author field at the root of the document.

The following rules demonstrate how to use the ValueFormat operation to change the format of dates. The only format that you can convert date values into is the IDOL AUTNDATE format. The first rule transforms the value of a field named CreatedDate. The second rule transforms the value of an attribute named Created, on a field named Date.

```
<FieldStandardization>
  <Field name="CreatedDate">
    <ValueFormat type="autndate" format="YYYY-SHORTMONTH-DD HH:NN:SS"/>
  </Field>
  <Field name="Date">
    <Attribute name="Created">
      <ValueFormat type="autndate" format="YYYY-SHORTMONTH-DD HH:NN:SS"/>
    </Attribute>
  </Field>
</FieldStandardization>
```

As demonstrated by this example, you can select field attributes to process in a similar way to selecting fields.

You must select attributes using either a fixed name or a regular expression:

Select a field attribute by name	<Attribute name="MyAttribute">
Select attributes that match a regular expression	<Attribute nameRegex=".*">

You can then add a restriction to limit the attributes that are processed:

Process an attribute only if its value matches a fixed value	<Attribute name="MyAttribute" matches="abc">
Process an attribute only if its value matches a regular expression	<Attribute name="MyAttribute" matchesRegex=".*">
Process an attribute only if its value contains a match to a regular expression	<Attribute name="MyAttribute" containsRegex="\w+">

The following rule moves all of the attributes of a field to sub fields, if the parent field has no value. The id attribute on the first Field element provides a name to a matching field so that it can be referred to by later operations. The GetName and GetValue operations save the name and value of a selected field or attribute (in this case an attribute) into variables (in this case '\$name' and '\$value') which can be used by later operations. The AddField operation uses the variables to add a new field at the selected location (the field identified by id="parent").

```
<FieldStandardization>
  <Field pathRegex=".*" matches="" id="parent">
    <Attribute nameRegex=".*">
      <GetName var="name"/>
      <GetValue var="value"/>
      <Field fieldId="parent">
        <AddField name="'$name'" value="'$value'"/>
      </Field>
    </Attribute>
  </Field>
</FieldStandardization>
```

```
        </Attribute>  
    </Field>  
</FieldStandardization>
```

The following rule demonstrates how to move all of the subfields of `UnwantedParentField` to the root of the document, and then delete the field `UnwantedParentField`.

```
<FieldStandardization id="root">  
    <Product key="MyConnector">  
        <Field name="UnwantedParentField">  
            <Field nameRegex=".*">  
                <Move destId="root"/>  
            </Field>  
            <Delete/>  
        </Field>  
    </Product>  
</FieldStandardization>
```

Run Lua Scripts

IDOL Connectors can run custom scripts written in Lua, an embedded scripting language. You can use Lua scripts to process documents that are created by a connector, before they are sent to CFS and indexed into IDOL Server. For example, you can:

- Add or modify document fields.
- Manipulate the information that is indexed into IDOL.
- Call out to an external service, for example to alert a user.

There might be occasions when you do not want to send documents to a CFS. For example, you might use the `Collect` action to retrieve documents from one repository and then insert them into another. You can use a Lua script to transform the documents from the source repository so that they can be accepted by the destination repository.

To run a Lua script from a connector, use one of the following methods:

- Set the `IngestActions` configuration parameter in the connector's configuration file. For information about how to do this, see [Run a Lua Script using an Ingest Action, on page 69](#). The connector runs ingest actions on documents before they are sent for ingestion.
- Set the `IngestActions` action parameter when using the `Synchronize` action.
- Set the `InsertActions` configuration parameter in the connector's configuration file. The connector runs insert actions on documents before they are inserted into a repository.
- Set the `CollectActions` action parameter when using the `Collect` action.

Write a Lua Script

A Lua script that is run from a connector must have the following structure:

```
function handler(config, document, params)
    ...
end
```

The handler function is called for each document and is passed the following arguments:

Argument	Description
config	A LuaConfig object that you can use to retrieve the values of configuration parameters from the connector's configuration file.
document	A LuaDocument object. The document object is an internal representation of the document being processed. Modifying this object changes the document.
params	The params argument is a table that contains additional information provided by the connector: <ul style="list-style-type: none"> • TYPE. The type of task being performed. The possible values are ADD, UPDATE, DELETE, or COLLECT. • SECTION. The name of the section in the configuration file that contains configuration parameters for the task. • FILENAME. The document filename. The Lua script can modify this file, but must not delete it. • OWNFILE. Indicates whether the connector (and CFS) has ownership of the file. A value of true means that CFS deletes the file after it has been processed.

The following script demonstrates how you can use the config and params arguments:

```
function handler(config, document, params)
    -- Write all of the additional information to a log file
    for k,v in pairs(params) do
        log("logfile.txt", k..": "..tostring(v))
    end

    -- The following lines set variables from the params argument
    type = params["TYPE"]
    section = params["SECTION"]
    filename = params["FILENAME"]

    -- Read a configuration parameter from the configuration file
    -- If the parameter is not set, "DefaultValue" is returned
    val = config:getValue(section, "Parameter", "DefaultValue")

    -- If the document is not being deleted, set the field FieldName
    -- to the value of the configuration parameter
    if type ~= "DELETE" then
        document:setFieldValue("FieldName", val)
    end

    -- If the document has a file (that is, not just metadata),
    -- copy the file to a new location and write a stub idx file
```

```
-- containing the metadata.  
if filename ~= "" then  
    copytofilename = "./out/"..create_uuid(filename)  
    copy_file(filename, copytofilename)  
    document:writeStubIdx(copytofilename..".idx")  
end  
  
return true  
end
```

For the connector to continue processing the document, the `handler` function must return `true`. If the function returns `false`, the document is discarded.

TIP:

You can write a library of useful functions to share between multiple scripts. To include a library of functions in a script, add the code `dofile("library.lua")` to the top of the lua script, outside of the `handler` function.

Run a Lua Script using an Ingest Action

To run a Lua script on documents that are sent for ingestion, use an Ingest Action.

To run a Lua script using an Ingest Action

1. Open the connector's configuration file.
2. Find one of the following sections in the configuration file:
 - To run a Lua script on all documents retrieved by a specific task, find the `[TaskName]` section.
 - To run a Lua script on all documents that are sent for ingestion, find the `[Ingestion]` section.

NOTE:

If you set the `IngestActions` parameter in a `[TaskName]` section, the connector does not run any `IngestActions` set in the `[Ingestion]` section for that task.

3. Use the `IngestActions` parameter to specify the path to your Lua script. For example:

```
IngestActions=LUA:C:\Autonomy\myScript.lua
```

4. Save and close the configuration file.

Related Topics

- [Write a Lua Script, on page 67](#)

Example Lua Scripts

This section contains example Lua scripts.

- [Add a Field to a Document, on the next page](#)
- [Merge Document Fields, on the next page](#)

Add a Field to a Document

The following script demonstrates how to add a field named “MyField” to a document, with a value of “MyValue”.

```
function handler(config, document, params)
    document:addField("MyField", "MyValue");
    return true;
end
```

The following script demonstrates how to add the field AUTN_NEEDS_MEDIA_SERVER_ANALYSIS to all JPEG, TIFF and BMP documents. This field indicates to CFS that the file should be sent to a Media Server for analysis (you must also define the MediaServerAnalysis task in the CFS configuration file).

The script finds the file type using the DREREFERENCE document field, so this field must contain the file extension for the script to work correctly.

```
function handler(config, document, params)
    local extensions_for_ocr = { jpg = 1 , tif = 1, bmp = 1 };
    local filename = document:getFieldValue("DREREFERENCE");
    local extension, extension_found = filename:gsub("^.*%.(%w+)$", "%1", 1);

    if extension_found > 0 then
        if extensions_for_ocr[extension:lower()] ~= nil then
            document:addField("AUTN_NEEDS_MEDIA_SERVER_ANALYSIS", "");
        end
    end

    return true;
end
```

Merge Document Fields

This script demonstrates how to merge the values of document fields.

When you extract data from a repository, the connector can produce documents that have multiple values for a single field, for example:

```
#DREFIELD ATTACHMENT="attachment.txt"
#DREFIELD ATTACHMENT="image.jpg"
#DREFIELD ATTACHMENT="document.pdf"
```

This script shows how to merge the values of these fields, so that the values are contained in a single field, for example:

```
#DREFIELD ATTACHMENTS="attachment.txt, image.jpg, document.pdf"
```

Example Script

```
function handler(config, document, params)
    onefield(document,"ATTACHMENT","ATTACHMENTS")
    return true;
end

function onefield(document,existingfield,newfield)
    if document:hasField(existingfield) then
        local values = { document:getFieldValues(existingfield) }

        local newfieldvalue=""
        for i,v in ipairs(values) do
            if i>1 then
                newfieldvalue = newfieldvalue ..", "
            end

            newfieldvalue = newfieldvalue..v
        end

        document:addField(newfield,newfieldvalue)
    end

    return true;
end
```

Chapter 9: Ingestion

After a connector finds new documents in a repository, or documents that have been updated or deleted, it sends this information to another component called the *ingestion target*. This section describes where you can send the information retrieved by the File System Connector, and how to configure the ingestion target.

- Introduction 72
- Send Data to Connector Framework Server 73
- Send Data to Haven OnDemand 74
- Send Data to Another Repository 76
- Index Documents Directly into IDOL Server 76
- Index Documents into Vertica 78
- Send Data to a MetaStore 80
- Run a Lua Script after Ingestion 81

Introduction

A connector can send information to a single ingestion target, which could be:

- **Connector Framework Server.** To process information and then index it into IDOL, Haven OnDemand, or Vertica, send the information to a Connector Framework Server (CFS). Any files retrieved by the connector are *imported* using KeyView, which means the information contained in the files is converted into a form that can be indexed. If the files are containers that contain *subfiles*, these are extracted. You can manipulate and enrich documents using Lua scripts and automated tasks such as field standardization, image analysis, and speech-to-text processing. CFS can index your documents into one or more indexes. For more information about CFS, refer to the *Connector Framework Server Administration Guide*.

- **Haven OnDemand.** You can index documents directly into a Haven OnDemand text index. Haven OnDemand can extract text, metadata, and subfiles from over 1000 different file formats, so you might not need to send documents to CFS.
- **Another Connector.** Use another connector to keep another repository up-to-date. When a connector receives documents, it inserts, updates, or deletes the information in the repository. For example, you could use an Exchange Connector to extract information from Microsoft Exchange, and send the documents to a Notes Connector so that the information is inserted, updated, or deleted in the Notes repository.

NOTE:
The destination connector can only insert, update, and delete documents if it supports the `insert`, `update`, and `delete` fetch actions.

In most cases HPE recommends ingesting documents through CFS, so that KeyView can extract content from any files retrieved by the connector and add this information to your documents. You can also use CFS to manipulate and enrich documents before they are indexed. However, if required you can configure the connector to index documents directly into:

- **IDOL Server.** You might index documents directly into IDOL Server when your connector produces metadata-only documents (documents that do not have associated files). In this case there is no need for the documents to be imported. Connectors that can produce metadata-only documents include ODBC Connector and Oracle Connector.
- **Vertica.** The metadata extracted by connectors is structured information held in structured fields, so you might use Vertica to analyze this information.
- **MetaStore.** You can index document metadata into a MetaStore for records management.

Send Data to Connector Framework Server

This section describes how to configure ingestion into Connector Framework Server (CFS).

To send data to a CFS

1. Stop the connector.
2. Open the connector's configuration file in a text editor.
3. In the [Ingestion] section, set the following parameters:

`EnableIngestion` To enable ingestion, set this parameter to `true`.

`IngesterType` To send data to CFS, set this parameter to `CFS`.

`IngestHost` The host name or IP address of the CFS.

`IngestPort` The ACI port of the CFS.

For example:

```
[Ingestion]
EnableIngestion=True
IngesterType=CFS
IngestHost=localhost
IngestPort=7000
```

4. (Optional) If you are sending documents to CFS for indexing into IDOL Server, set the `IndexDatabase` parameter. When documents are indexed, IDOL adds each document to the database specified in the document's `DREDBNAME` field. The connector sets this field for each document, using the value of `IndexDatabase`.

`IndexDatabase` The name of the IDOL database into which documents are indexed. Ensure that this database exists in the IDOL Server configuration file.

- To index all documents retrieved by the connector into the same IDOL database, set this parameter in the [Ingestion] section.
- To use a different database for documents retrieved by each task, set this parameter in the

TaskName section.

5. Save and close the configuration file.

Send Data to Haven OnDemand

This section describes how to configure ingestion into Haven OnDemand. File System Connector can index documents into a Haven OnDemand text index, or send the documents to a Haven OnDemand combination which can perform additional processing and then index the documents into a text index.

NOTE:

Haven OnDemand combinations do not accept binary files, so any documents that have associated binary files are indexed directly into a text index and cannot be sent to a combination.

Prepare Haven OnDemand

Before you can send documents to Haven OnDemand, you must create a text index. For information about how to create text indexes, refer to the [Haven OnDemand documentation](#).

Before you can send documents to a Haven OnDemand combination endpoint, the combination must exist. File System Connector requires your combination to accept the following input parameters, and produce the following output.

Input Parameters

Name	Type	Description
json	any	A JSON object that contains a single attribute 'documents' that is an array of document objects.
index	string	The name of the text index that you want the combination to add documents to. File System Connector uses the value of the parameter <code>HavenOnDemandIndexName</code> to set this value.
duplicate_mode	string	Specifies how to handle duplicates when adding documents to the text index. File System Connector uses the value of the parameter <code>HavenOnDemandDuplicateMode</code> to set this value.

Output

Name	Type	Description
result	any	The result of the call to <code>AddToTextIndex</code> made by the combination.

Send Data to Haven OnDemand

This section describes how to send documents to Haven OnDemand.

To send data to Haven OnDemand

1. Stop the connector.
2. Open the connector's configuration file in a text editor.
3. In the [Ingestion] section, set the following parameters:

EnableIngestion	To enable ingestion, set this parameter to <code>true</code> .
IngesterType	To send data to Haven OnDemand, set this parameter to <code>HavenOnDemand</code> .
HavenOnDemandApiKey	Your Haven OnDemand API key. You can obtain the key from your Haven OnDemand account.
HavenOnDemandIndexName	The name of the Haven OnDemand text index to index documents into.
IngestSSLConfig	The name of a section in the connector's configuration file that contains SSL settings. The connection to Haven OnDemand must be made over TLS. For more information about sending documents to the ingestion server over TLS, see Configure Outgoing SSL Connections, on page 29 .
HavenOnDemandCombinationName	(Optional) The name of the Haven OnDemand combination to send documents to. If you set this parameter, File System Connector sends documents to the combination endpoint instead of indexing them directly into the text index.

NOTE:

Haven OnDemand combinations do not accept binary files. Therefore any document that has an associated binary file is indexed directly into the text index.

If you don't set this parameter, File System Connector indexes all documents directly into the text index specified by `HavenOnDemandIndexName`.

For example:

```
[Ingestion]
EnableIngestion=True
IngesterType=HavenOnDemand
HavenOnDemandApiKey=[Your API Key]
HavenOnDemandIndexName=MyTextIndex
IngestSSLConfig=SSLOptions
HavenOnDemandCombinationName=MyCombination

[SSLOptions]
SSLMethod=TLSV1
```

4. Save and close the configuration file.

Send Data to Another Repository

You can configure a connector to send the information it retrieves to another connector. When the destination connector receives the documents, it inserts them into another repository. When documents are updated or deleted in the source repository, the source connector sends this information to the destination connector so that the documents can be updated or deleted in the other repository.

NOTE:

The destination connector can only insert, update, and delete documents if it supports the insert, update, and delete fetch actions.

To send data to another connector for ingestion into another repository

1. Stop the connector.
2. Open the connector's configuration file in a text editor.
3. In the [Ingestion] section, set the following parameters:

<code>EnableIngestion</code>	To enable ingestion, set this parameter to <code>true</code> .
<code>IngesterType</code>	To send data to another repository, set this parameter to <code>Connector</code> .
<code>IngestHost</code>	The host name or IP address of the machine hosting the destination connector.
<code>IngestPort</code>	The ACI port of the destination connector.
<code>IngestActions</code>	Set this parameter so that the source connector runs a Lua script to convert documents into form that can be used with the destination connector's insert action. For information about the required format, refer to the Administration Guide for the destination connector.

For example:

```
[Ingestion]
EnableIngestion=True
IngesterType=Connector
IngestHost=AnotherConnector
IngestPort=7010
IngestActions=Lua:transformation.lua
```

4. Save and close the configuration file.

Index Documents Directly into IDOL Server

This section describes how to index documents from a connector directly into IDOL Server.

TIP:

In most cases, HPE recommends sending documents to a Connector Framework Server

(CFS). CFS extracts metadata and content from any files that the connector has retrieved, and can manipulate and enrich documents before they are indexed. CFS also has the capability to insert documents into more than one index, for example IDOL Server and a Vertica database. For information about sending documents to CFS, see [Send Data to Connector Framework Server, on page 73](#)

To index documents directly into IDOL Server

1. Stop the connector.
2. Open the connector's configuration file in a text editor.
3. In the [Ingestion] section, set the following parameters:

EnableIngestion To enable ingestion, set this parameter to **true**.

IngesterType To send data to IDOL Server, set this parameter to **Indexer**.

IndexDatabase The name of the IDOL database to index documents into.

For example:

```
[Ingestion]
EnableIngestion=True
IngesterType=Indexer
IndexDatabase=News
```

4. In the [Indexing] section of the configuration file, set the following parameters:

IndexerType To send data to IDOL Server, set this parameter to **IDOL**.

Host The host name or IP address of the IDOL Server.

Port The IDOL Server ACI port.

SSLConfig (Optional) The name of a section in the connector's configuration file that contains SSL settings for connecting to IDOL.

For example:

```
[Indexing]
IndexerType=IDOL
Host=10.1.20.3
Port=9000
SSLConfig=SSLOptions
```

```
[SSLOptions]
SSLMethod=SSLV23
```

5. Save and close the configuration file.

Index Documents into Vertica

File System Connector can index documents into Vertica, so that you can run queries on structured fields (document metadata).

Depending on the metadata contained in your documents, you could investigate the average age of documents in a repository. You might want to answer questions such as: How much time has passed since the documents were last updated? How many files are regularly updated? Does this represent a small proportion of the total number of documents? Who are the most active users?

TIP:

In most cases, HPE recommends sending documents to a Connector Framework Server (CFS). CFS extracts metadata and content from any files that the connector has retrieved, and can manipulate and enrich documents before they are indexed. CFS also has the capability to insert documents into more than one index, for example IDOL Server and a Vertica database. For information about sending documents to CFS, see [Send Data to Connector Framework Server, on page 73](#)

Prerequisites

- File System Connector supports indexing into Vertica 7.1 and later.
- You must install the appropriate Vertica ODBC drivers (version 7.1 or later) on the machine that hosts File System Connector. If you want to use an ODBC Data Source Name (DSN) in your connection string, you will also need to create the DSN. For more information about installing Vertica ODBC drivers and creating the DSN, refer to the [HPE Vertica documentation](#).

New, Updated and Deleted Documents

When documents are indexed into Vertica, File System Connector adds a timestamp that contains the time when the document was indexed. The field is named `VERTICA_INDEXER_TIMESTAMP` and the timestamp is in the format `YYYY-MM-DD HH:NN:SS`.

When a document in a data repository is modified, File System Connector adds a new record to the database with a new timestamp. All of the fields are populated with the latest data. The record describing the older version of the document is not deleted. You can create a projection to make sure your queries only return the latest record for a document.

When File System Connector detects that a document has been deleted from a repository, the connector inserts a new record into the database. The record contains only the `DREREFERENCE` and the field `VERTICA_INDEXER_DELETED` set to `TRUE`.

Fields, Sub-Fields, and Field Attributes

Documents that are created by connectors can have multiple levels of fields, and field attributes. A database table has a flat structure, so this information is indexed into Vertica as follows:

- Document fields become columns in the flex table. An IDOL document field and the corresponding database column have the same name.
- Sub-fields become columns in the flex table. A document field named `my_field` with a sub-field named `subfield` results in two columns, `my_field` and `my_field.subfield`.
- Field attributes become columns in the flex table. A document field named `my_field`, with an attribute named `my_attribute` results in two columns, `my_field` holding the field value and `my_field.my_attribute` holding the attribute value.

Prepare the Vertica Database

Indexing documents into a standard database is problematic, because documents do not have a fixed schema. A document that represents an image has different metadata fields to a document that represents an e-mail message. Vertica databases solve this problem with *flex tables*. You can create a flex table without any column definitions, and you can insert a record regardless of whether a referenced column exists.

You must create a flex table before you index data into Vertica.

When creating the table, consider the following:

- Flex tables store entire records in a single column named `__raw__`. The default maximum size of the `__raw__` column is 128K. You might need to increase the maximum size if you are indexing documents with large amounts of metadata.
- Documents are identified by their DREREFERENCE. HPE recommends that you do not restrict the size of any column that holds this value, because this could result in values being truncated. As a result, rows that represent different documents might appear to represent the same document. If you do restrict the size of the DREREFERENCE column, ensure that the length is sufficient to hold the longest DREREFERENCE that might be indexed.

To create a flex table without any column definitions, run the following query:

```
create flex table my_table();
```

To improve query performance, create real columns for the fields that you query frequently. For documents indexed by a connector, this is likely to include the DREREFERENCE:

```
create flex table my_table(DREREFERENCE varchar NOT NULL);
```

You can add new column definitions to a flex table at any time. Vertica automatically populates new columns with values for existing records. The values for existing records are extracted from the `__raw__` column.

For more information about creating and using flex tables, refer to the [HPE Vertica Documentation](#) or contact HPE Vertica technical support.

Send Data to Vertica

To send documents to a Vertica database, follow these steps.

To send data to Vertica

1. Stop the connector.
2. Open the connector's configuration file in a text editor.
3. In the [Ingestion] section, set the following parameters:

`EnableIngestion` To enable ingestion, set this parameter to `true`.

`IngesterType` To send data to a Vertica database, set this parameter to `Indexer`.

For example:

```
[Ingestion]
EnableIngestion=TRUE
IngesterType=Indexer
```

4. In the [Indexing] section, set the following parameters:

`IndexerType` To send data to a Vertica database, set this parameter to `Library`.

`LibraryDirectory` The directory that contains the library to use to index data.

`LibraryName` The name of the library to use to index data. You can omit the `.dll` or `.so` file extension. Set this parameter to `verticaIndexer`.

`ConnectionString` The connection string to use to connect to the Vertica database.

`TableName` The name of the table in the Vertica database to index the documents into. The table must be a flex table and must exist before you start indexing documents. For more information, see [Prepare the Vertica Database, on the previous page](#).

For example:

```
[Indexing]
IndexerType=Library
LibraryDirectory=indexerdlls
LibraryName=verticaIndexer
ConnectionString=DSN=VERTICA
TableName=my_flex_table
```

5. Save and close the configuration file.

Send Data to a MetaStore

You can configure a connector to send documents to a MetaStore. When you send data to a Metastore, any files associated with documents are ignored.

TIP:

In most cases, HPE recommends sending documents to a Connector Framework Server (CFS). CFS extracts metadata and content from any files that the connector has retrieved, and can manipulate and enrich documents before they are indexed. CFS also has the capability to insert documents into more than one index, for example IDOL Server and a MetaStore. For information about sending documents to CFS, see [Send Data to Connector Framework Server, on page 73](#)

To send data to a MetaStore

1. Stop the connector.
2. Open the connector's configuration file in a text editor.
3. In the [Ingestion] section, set the following parameters:

`EnableIngestion` To enable ingestion, set this parameter to `true`.

`IngesterType` To send data to a MetaStore, set this parameter to `Indexer`.

For example:

```
[Ingestion]
EnableIngestion=True
IngesterType=Indexer
```

4. In the [Indexing] section, set the following parameters:

`IndexerType` To send data to a MetaStore, set this parameter to `MetaStore`.

`Host` The host name of the machine hosting the MetaStore.

`Port` The port of the MetaStore.

For example:

```
[Indexing]
IndexerType=Metastore
Host=MyMetaStore
Port=8000
```

5. Save and close the configuration file.

Run a Lua Script after Ingestion

You can configure the connector to run a Lua script after batches of documents are successfully sent to the ingestion server. This can be useful if you need to log information about documents that were processed, for monitoring and reporting purposes.

To configure the file name of the Lua script to run, set the `IngestBatchActions` configuration parameter in the connector's configuration file.

- To run the script for all batches of documents that are ingested, set the parameter in the [Ingestion] section.
- To run the script for batches of documents retrieved by a specific task, set the parameter in the

[*TaskName*] section.

NOTE:

If you set the parameter in a [*TaskName*] section, the connector does not run any scripts specified in the [Ingestion] section for that task.

For example:

```
[Ingestion]
IngestBatchActions0=LUA:./scripts/myScript.lua
```

For more information about this parameter, refer to the *File System Connector Reference*.

The Lua script must have the following structure:

```
function batchhandler(documents, ingesttype)
    ...
end
```

The `batchhandler` function is called after each batch of documents is sent to the ingestion server. The function is passed the following arguments:

Argument	Description
<code>documents</code>	A table of document objects, where each object represents a document that was sent to the ingestion server. A document object is an internal representation of a document. You can modify the document object and this changes the document. However, as the script runs after the documents are sent to the ingestion server, any changes you make are not sent to CFS or IDOL.
<code>ingesttype</code>	A string that contains the ingest type for the documents. The <code>batchhandler</code> function is called multiple times if different document types are sent.

For example, the following script prints the ingest type (ADD, DELETE, or UPDATE) and the reference for all successfully processed documents to `stdout`:

```
function batchhandler(documents, ingesttype)
    for i,document in ipairs(documents) do
        local ref = document:getReference()
        print(ingesttype..": "..ref)
    end
end
```

Chapter 10: Monitor the Connector

This section describes how to monitor the connector.

• IDOL Admin	83
• View Connector Statistics	85
• Use the Connector Logs	86
• Monitor the Progress of a Task	88
• Set Up Event Handlers	90
• Set Up Performance Monitoring	92
• Set Up Document Tracking	94

IDOL Admin

IDOL Admin is an administration interface for performing ACI server administration tasks, such as gathering status information, monitoring performance, and controlling the service. IDOL Admin provides an alternative to constructing actions and sending them from your web browser.

Prerequisites

By default, the latest version of File System Connector should include the `admin.dat` file that is required to run IDOL Admin. If you do not have this file, you must download it separately.

Supported Browsers

IDOL Admin supports the following browsers:

- Internet Explorer 11 and later
- Edge
- Chrome (latest version)
- Firefox (latest version)

Install IDOL Admin

You must install IDOL Admin on the same host that the ACI server or component is installed on. To set up a component to use IDOL Admin, you must configure the location of the `admin.dat` file and enable Cross Origin Resource Sharing.

To install IDOL Admin

1. Stop the ACI server.
2. Save the `admin.dat` file to any directory on the host.
3. Using a text editor, open the ACI server or component configuration file. For the location of the configuration file, see the ACI server documentation.
4. In the `[Paths]` section of the configuration file, set the `AdminFile` parameter to the location of the `admin.dat` file. If you do not set this parameter, the ACI server attempts to find the `admin.dat` file in its working directory when you call the IDOL Admin interface.
5. Enable Cross Origin Resource Sharing.
6. In the `[Service]` section, add the `Access-Control-Allow-Origin` parameter and set its value to the URLs that you want to use to access the interface.

Each URL must include:

- the `http://` or `https://` prefix

NOTE:

URLs can contain the `https://` prefix if the ACI server or component has SSL enabled.

- The host that IDOL Admin is installed on
- The ACI port of the component that you are using IDOL Admin for

Separate multiple URLs with spaces.

For example, you could specify different URLs for the local host and remote hosts:

```
Access-Control-Allow-Origin=http://localhost:9010  
http://Computer1.Company.com:9010
```

Alternatively, you can set `Access-Control-Allow-Origin=*`, which allows you to access IDOL Admin using any valid URL (for example, `localhost`, direct IP address, or the host name). The wildcard character (`*`) is supported only if no other entries are specified.

If you do not set the `Access-Control-Allow-Origin` parameter, IDOL Admin can communicate only with the server's ACI port, and not the index or service ports.

7. Start the ACI server.

You can now access IDOL Admin (see [Access IDOL Admin, below](#)).

Access IDOL Admin

You access IDOL Admin from a web browser. You can access the interface only through URLs that are set in the `Access-Control-Allow-Origin` parameter in the ACI server or component configuration file. For more information about configuring URL access, see [Install IDOL Admin, on the previous page](#).

To access IDOL Admin from the host that it is installed on

- Type the following URL into the address bar of your web browser:

```
http://localhost:port/action=admin
```

where `port` is the ACI server or component ACI port.

To access IDOL Admin from a different host

- Type the following URL into the address bar of your web browser:

```
http://host:port/action=admin
```

where:

host is the name or IP address of the host that IDOL Admin is installed on.

port is the ACI server or component ACI port of the IDOL Admin host.

View Connector Statistics

File System Connector collects statistics about the work it has completed. The statistics that are available depend on the connector you are using, but all connectors provide information about the number and frequency of ingest-adds, ingest-updates, and ingest-deletes.

To view connector statistics

- Use the `GetStatistics` service action, for example:

```
http://host:serviceport/action=GetStatistics
```

where *host* is the host name or IP address of the machine where the connector is installed, and *serviceport* is the connector's service port.

For information about the statistics that are returned, refer to the documentation for the `GetStatistics` service action.

The connector includes an XSL template (`ConnectorStatistics.tpl`) that you can use to visualize the statistics. You can use the template by adding the `template` parameter to the request:

```
http://host:serviceport/action=GetStatistics&template=ConnectorStatistics
```

When you are using the `ConnectorStatistics` template, you can also add the `filter` parameter to the request to return specific statistics. The `filter` parameter accepts a regular expression that matches against the string `autnid:name`, where `autnid` and `name` are the values of the corresponding attributes in the XML returned by the `GetStatistics` action. For example, the following request returns statistics only for synchronize actions:

```
http://host:serviceport/action=GetStatistics&template=ConnectorStatistics  
&filter=^synchronize:
```

The following request returns statistics only for the task `mytask`:

```
http://host:serviceport/action=GetStatistics&template=ConnectorStatistics  
&filter=:mytask:
```

The following image shows some example statistics returned by a connector:

Above each chart is a title, for example SYNCHRONIZE :MYTASK, that specifies the action and task to which the statistics belong.

You can see from the example that in the last 60 seconds, the connector has generated an average of approximately 0.4 ingest-adds per second. In the charts, partially transparent bars indicate that the connector has not completed collecting information for those time intervals. The information used to generate statistics is stored in memory, so is lost if you stop the connector.

The following information is presented above the chart for each statistic:

- **Total** is a running total since the connector started. In the example above, there have been 70 ingest-adds in total.
- **Current Total** is the total for the actions that are currently running. In the example above, the synchronize action that is running has resulted in 30 ingest-adds being sent to CFS.
- **Previous Total** provides the totals for previous actions. In the example above, the previous synchronize cycle resulted in 40 ingest-adds. To see the totals for the 24 most recent actions, hover the mouse pointer over the value.

Use the Connector Logs

As the File System Connector runs, it outputs messages to its logs. Most log messages occur due to normal operation, for example when the connector starts, receives actions, or sends documents for ingestion. If the connector encounters an error, the logs are the first place to look for information to help troubleshoot the problem.

The connector separates messages into the following message types, each of which relates to specific features:

Log Message Type	Description
------------------	-------------

Action	Logs actions that are received by the connector, and related messages.
Application	Logs application-related occurrences, such as when the connector starts.
Collect	Messages related to the Collect fetch action.
Delete	Messages related to the Delete fetch action.
Identifiers	Messages related to the Identifiers fetch action.
Insert	Messages related to the Insert fetch action.
Synchronize	Messages related to the Synchronize fetch action.
Update	Messages related to the Update fetch action.
View	Messages related to the View action.

Customize Logging

You can customize logging by setting up your own *log streams*. Each log stream creates a separate log file in which specific log message types (for example, action, index, application, or import) are logged.

To set up log streams

1. Open the File System Connector configuration file in a text editor.
2. Find the [Logging] section. If the configuration file does not contain a [Logging] section, add one.
3. In the [Logging] section, create a list of the log streams that you want to set up, in the format *N=LogStreamName*. List the log streams in consecutive order, starting from 0 (zero). For example:

```
[Logging]
LogLevel=FULL
LogDirectory=logs
0=ApplicationLogStream
1=ActionLogStream
```

You can also use the [Logging] section to configure any default values for logging configuration parameters, such as LogLevel. For more information, see the *File System Connector Reference*.

4. Create a new section for each of the log streams. Each section must have the same name as the log stream. For example:

```
[ApplicationLogStream]
[ActionLogStream]
```

5. Specify the settings for each log stream in the appropriate section. You can specify the type of logging to perform (for example, full logging), whether to display log messages on the console, the maximum size of log files, and so on. For example:

```
[ApplicationLogStream]
LogTypeCSVs=application
```

```
LogFile=application.log
LogHistorySize=50
LogTime=True
LogEcho=False
LogMaxSizeKBs=1024

[ActionLogStream]
LogTypeCSVs=action
LogFile=logs/action.log
LogHistorySize=50
LogTime=True
LogEcho=False
LogMaxSizeKBs=1024
```

6. Save and close the configuration file. Restart the service for your changes to take effect.

Monitor the Progress of a Task

This section describes how to monitor the progress of a task.

NOTE:

You can only monitor the progress of a synchronize task. Progress reports are not available for other actions.

To monitor the progress of a task

- Send the following action to the connector:

```
action=QueueInfo&QueueName=fetch&QueueAction=progress&Token=...
```

where,

Token The token of the task that you want to monitor. If you started the task by sending an action to the connector, the token was returned in the response. If the connector started the task according to the schedule in its configuration file, you can use the `QueueInfo` action to find the token (use `/action=QueueInfo&QueueName=fetch&QueueAction=getstatus`).

The connector returns the progress report, inside the `<progress>` element of the response. The following example is from a File System Connector.

```
<autnresponse>
  <action>QUEUEINFO</action>
  <response>SUCCESS</response>
  <responsedata>
    <action>
      <token>MTAuMi4xMDUuMTAzOjEyMzQ6RkVUQ0g6MTAxNzM0Mzg0Q0==</token>
      <status>Processing</status>
      <progress>
        <building_mode>>false</building_mode>
        <percent>7.5595</percent>
        <time_processing>18</time_processing>
      </progress>
    </action>
  </responsedata>
</autnresponse>
```

```
<estimated_time_remaining>194</estimated_time_remaining>
<stage title="MYTASK" status="Processing" weight="1" percent="7.5595">
  <stage title="Ingestion" status="Processing" weight="999"
percent="7.567">
    <stage title="C:\Test Files\" status="Processing" weight="6601"
percent="7.567" progress="0" maximum="6601">
      <stage title="Folder01" status="Processing" weight="2317"
percent="43.116" progress="999" maximum="2317"/>
        <stage title="Folder02" status="Pending" weight="2567"/>
        <stage title="Folder03" status="Pending" weight="1715"/>
        <stage title="." status="Pending" weight="2"/>
      </stage>
    </stage>
  <stage title="Deletion" status="Pending" weight="1"/>
</stage>
</progress>
</action>
</responsedata>
</autnresponse>
```

To read the progress report

The information provided in the progress report is unique to each connector. For example, the File System Connector reports the progress of a synchronize task by listing the folders that require processing.

The progress report supplied by the connector can include several *stages*:

- A *stage* represents part of a task.
- A stage can have sub-stages. In the previous example, the stage "C:\Test Files\" has three stages that represent sub-folders ("Folder01", "Folder02", and "Folder03") and one stage that represents the contents of the folder itself ("."). You can limit the depth of the sub-stages in the progress report by setting the `MaxDepth` parameter in the `QueueInfo` action.
- The `weight` attribute indicates the amount of work included in a stage, relative to other stages at the same level.
- The `status` attribute shows the status of a stage. The status can be "Pending", "Processing", or "Finished".
- The `progress` attribute shows the number of items that have been processed for the stage.
- The `maximum` attribute shows the total number of items that must be processed to complete the stage.
- The `percent` attribute shows the progress of a stage (percentage complete). In the previous example, the progress report shows that MYTASK is 7.5595% complete.
- Finished stages are grouped, and pending stages are not expanded into sub-stages, unless you set the action parameter `AllStages=true` in the `QueueInfo` action.

Set Up Event Handlers

The fetch actions sent to a connector are asynchronous. Asynchronous actions do not run immediately, but are added to a queue. This means that the person or application that sends the action does not receive an immediate response. However, you can configure the connector to call an event handler when an asynchronous action starts, finishes, or encounters an error.

You can use an event handler to:

- return data about an event back to the application that sent the action.
- write event data to a text file, to log any errors that occur.

The connector can call an event handler for the following events:

OnStart	The <code>OnStart</code> event is called when the connector starts processing an asynchronous action.
OnFinish	The <code>OnFinish</code> event is called when the connector successfully finishes processing an asynchronous action.
OnError	The <code>OnError</code> event is called when an asynchronous action fails and cannot continue.
OnErrorReport	The <code>OnErrorReport</code> event is called when an asynchronous action encounters an error, but the action continues. This event is not available for every connector.

Event Handlers

You can configure the connector to call an internal event handler, or write your own event handler. Connectors include the following internal event handlers.

TextFileHandler

The `TextFileHandler` writes event data to a text file.

HttpHandler

The `HttpHandler` sends event data to a URL.

LuaHandler

The `LuaHandler` runs a Lua script. The event data is passed into the script. The script must have the following form:

```
function handler(request, xml)
    ...
end
```

- request is a table holding the request parameters.
- xml is a string holding the response to the request.

Configure an Event Handler

To configure an event handler, follow these steps.

To configure an event handler

1. Stop the connector.
2. Open the connector's configuration file in a text editor.
3. Use the `OnStart`, `OnFinish`, `OnErrorReport`, or `OnError` parameter to specify the name of a section in the configuration file that contains event handler settings for the corresponding event.
 - To run an event handler for all actions, set these parameters in the `[Actions]` section. For example:

```
[Actions]
OnStart=NormalEvents
OnFinish=NormalEvents
OnErrorReport=ErrorEvents
OnError=ErrorEvents
```

- To run an event handler for specific actions, use the action name as a section in the configuration file. The following example runs an event handler when the *Fetch* action starts and finishes successfully:

```
[Fetch]
OnStart=NormalEvents
OnFinish=NormalEvents
```

4. Create a new section in the configuration file to contain the settings for your event handler. You must name the section using the name you specified with the `OnStart`, `OnFinish`, `OnErrorReport`, or `OnError` parameter.
5. In the new section, set the following parameters.

LibraryName (Required) The name of the library to use as the event handler. You can write your own event handler, or use one of the internal event handlers:

- To write event data to a text file, set this parameter to `TextFileHandler`, and then set the `FilePath` parameter to specify the path of the file.
- To send event data to a URL, set this parameter to `HttpHandler`, and then use the HTTP event handler parameters to specify the URL, proxy server settings, credentials and so on.
- To run a Lua script, set this parameter to `LuaHandler`, and then set the `LuaScript` parameter to specify the path to the Lua script.

For example:

```
[NormalEvents]
LibraryName=TextFileHandler
```

```
FilePath=./events.txt
```

```
[ErrorEvents]  
LibraryName=LuaHandler  
LuaScript=./error.lua
```

6. Save and close the configuration file.

Set Up Performance Monitoring

You can configure a connector to pause tasks temporarily if performance indicators on the local machine or a remote machine breach certain limits. For example, if there is a high load on the CPU or memory of the repository from which you are retrieving information, you might want the connector to pause until the machine recovers.

NOTE:

Performance monitoring is available on Windows platforms only. To monitor a remote machine, both the connector machine and remote machine must be running Windows.

Configure the Connector to Pause

To configure the connector to pause

1. Open the configuration file in a text editor.
2. Find the `[FetchTasks]` section, or a `[TaskName]` section.
 - To pause all tasks, use the `[FetchTasks]` section.
 - To specify settings for a single task, find the `[TaskName]` section for the task.
3. Set the following configuration parameters:

<code>PerfMonCounterNameN</code>	The names of the performance counters that you want the connector to monitor. You can use any counter that is available in the Windows <code>perfmon</code> utility.
<code>PerfMonCounterMinN</code>	The minimum value permitted for the specified performance counter. If the counter falls below this value, the connector pauses until the counter meets the limits again.
<code>PerfMonCounterMaxN</code>	The maximum value permitted for the specified performance counter. If the counter exceeds this value, the connector pauses until the counter meets the limits again.
<code>PerfMonAvgOverReadings</code>	(Optional) The number of readings that the connector averages before checking a performance counter against the specified limits. For example, if you set this parameter to 5, the connector averages the last five readings and pauses only if the average breaches the limits. Increasing this value makes the connector

less likely to pause if the limits are breached for a short time. Decreasing this value allows the connector to continue working faster following a pause.

PerfMonQueryFrequency (Optional) The amount of time, in seconds, that the connector waits between taking readings from a performance counter.

For example:

```
[FetchTasks]
PerfMonCounterName0=\\machine-hostname\Memory\Available MBytes
PerfMonCounterMin0=1024
PerfMonCounterMax0=1024000
PerfMonCounterName1=\\machine-hostname\Processor(_Total)\% Processor Time
PerfMonCounterMin1=0
PerfMonCounterMax1=70
PerfMonAvgOverReadings=5
PerfMonQueryFrequency=10
```

NOTE:

You must set both a minimum and maximum value for each performance counter. You can not set only a minimum or only a maximum.

4. Save and close the configuration file.

Determine if an Action is Paused

To determine whether an action has been paused for performance reasons, use the `QueueInfo` action:

```
/action=queueInfo&queueAction=getStatus&queueName=fetch
```

You can also include the optional `token` parameter to return information about a single action:

```
/action=queueInfo&queueAction=getStatus&queueName=fetch&token=...
```

The connector returns the status, for example:

```
<autnresponse>
  <action>QUEUEINFO</action>
  <response>SUCCESS</response>
  <responsedata>
    <actions>
      <action owner="2266112570">
        <status>Processing</status>
        <queued_time>2016-Jul-27 14:49:40</queued_time>
        <time_in_queue>1</time_in_queue>
        <process_start_time>2016-Jul-27 14:49:41</process_start_time>
        <time_processing>219</time_processing>
        <documentcounts>
          <documentcount errors="0" task="MYTASK"/>
        </documentcounts>
        <fetchaction>SYNCHRONIZE</fetchaction>
      </action>
    </actions>
  </responsedata>
</autnresponse>
```

```
<pausedforperformance>true</pausedforperformance>  
<token>...</token>  
</action>  
</actions>  
</responsedata>  
</autnresponse>
```

When the element `pausedforperformance` has a value of `true`, the connector has paused the task for performance reasons. If the `pausedforperformance` element is not present in the response, the connector has not paused the task.

Set Up Document Tracking

Document tracking reports metadata about documents when they pass through various stages in the indexing process. For example, when a connector finds a new document and sends it for ingestion, a document tracking event is created that shows the document has been added. Document tracking can help you detect problems with the indexing process.

You can write document tracking events to a database, log file, or IDOL Server. For information about how to set up a database to store document tracking events, refer to the *IDOL Server Administration Guide*.

To enable Document Tracking

1. Open the connector's configuration file.
2. Create a new section in the configuration file, named `[DocumentTracking]`.
3. In the new section, specify where the document tracking events are sent.
 - To send document tracking events to a database through ODBC, set the following parameters:

`Backend` To send document tracking events to a database, set this parameter to **Library**.

`LibraryPath` Specify the location of the ODBC document tracking library. This is included with IDOL Server.

`ConnectionString` The ODBC connection string for the database.

For example:

```
[DocumentTracking]  
Backend=Library  
LibraryPath=C:\Autonomy\IDOLServer\IDOL\modules\dt_odbc.d11  
ConnectionString=DSN=MyDatabase
```

- To send document tracking events to the connector's synchronize log, set the following parameters:

`Backend` To send document tracking events to the connector's logs, set this parameter to **Log**.

DatabaseName The name of the log stream to send the document tracking events to. Set this parameter to **synchronize**.

For example:

```
[DocumentTracking]  
Backend=Log  
DatabaseName=synchronize
```

- To send document tracking events to an IDOL Server, set the following parameters:

Backend To send document tracking events to an IDOL Server, set this parameter to **IDOL**.

TargetHost The host name or IP address of the IDOL Server.

TargetPort The index port of the IDOL Server.

For example:

```
[DocumentTracking]  
Backend=IDOL  
TargetHost=idol  
TargetPort=9001
```

For more information about the parameters you can use to configure document tracking, refer to the *File System Connector Reference*.

4. Save and close the configuration file.

Appendix A: Document Fields

The connector adds the following fields to each document that it ingests:

Field Name	Description
AUTN_IDENTIFIER	An identifier that allows a connector to extract the document from the repository again, for example during the collect or view actions.
AUTN_MODIFICATIONS	<p>Provides information about how many times an item has been modified. For example:</p> <pre><AUTN_MODIFICATIONS modified="3" modified_history="F09"/></pre> <p>This field is not supported by all connectors, so it might not be present, and might not include all of the attributes described below:</p> <ul style="list-style-type: none"> <code>modified</code> - the number of modifications that have been observed by the connector. This might be a minimum number; if an item is modified more than once between synchronize cycles the connector might only observe a single change (this depends on the information available from the repository). <code>modified_history</code> - the time intervals between recent modifications (up to 50, one character per interval, with the most recent change at the end of the list). To convert a character into a time duration: <ol style="list-style-type: none"> Convert the character to an integer, n, (0 to 61) by the position in this string: 0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZabcdefghijklmnopqrstuvwxyz. Calculate using floating point arithmetic $(13/9)^n$. Read the resulting number as a number of seconds giving the minimum duration. Due to rounding the actual value will be in the range $(13/9)^n$ to $(13/9)^{(n+1)}$. <p>For example, to read "F":</p> <ul style="list-style-type: none"> $n=15$, because "F" is the 16th character in the string above. $(13/9)^{15} = (1.44444\dots)^{15} = 248.6\dots$ This gives a minimum duration of 0:04:08. The full range would be 248.6 to 359.1 seconds, or a duration between 0:04:08 and 0:05:59. <code>attributesmodified</code> - the number of times the attributes of a file have been modified. This might be a minimum number; if an item is modified more than once between synchronize cycles the connector might only observe a single change (this depends on the information available from the repository). <code>attributesmodified_history</code> - the time intervals between attributes being modified. This field has the same format as <code>modified_history</code>.
DocTrackingId	An identifier used for document tracking functionality.
DRREFERENCE	A reference for the document. This is the standard IDOL reference field, which is used for deduplication.

Field Name	Description
source_connector_run_id	(Added only when <code>IngestSourceConnectorFields=TRUE</code>). The asynchronous action token of the <code>fetch</code> action that ingested the document.
source_connector_server_id	(Added only when <code>IngestSourceConnectorFields=TRUE</code>). A token that identifies the instance of the connector that retrieved the document (different installations of the same connector populate this field with different IDs). You can retrieve the UID of a connector through <code>action=GetVersion</code> .

Glossary

A

ACI (Autonomy Content Infrastructure)

A technology layer that automates operations on unstructured information for cross-enterprise applications. ACI enables an automated and compatible business-to-business, peer-to-peer infrastructure. The ACI allows enterprise applications to understand and process content that exists in unstructured formats, such as email, Web pages, Microsoft Office documents, and IBM Notes.

ACI Server

A server component that runs on the Autonomy Content Infrastructure (ACI).

ACL (access control list)

An ACL is metadata associated with a document that defines which users and groups are permitted to access the document.

action

A request sent to an ACI server.

active directory

A domain controller for the Microsoft Windows operating system, which uses LDAP to authenticate users and computers on a network.

C

Category component

The IDOL Server component that manages categorization and clustering.

Community component

The IDOL Server component that manages users and communities.

connector

An IDOL component (for example File System Connector) that retrieves information from a local or remote repository (for example, a file system, database, or Web site).

Connector Framework Server (CFS)

Connector Framework Server processes the information that is retrieved by connectors. Connector Framework Server uses KeyView to extract document content and metadata from over 1,000 different file types. When the information has been processed, it is sent to an IDOL Server or Distributed Index Handler (DIH).

Content component

The IDOL Server component that manages the data index and performs most of the search and retrieval operations from the index.

D

DAH (Distributed Action Handler)

DAH distributes actions to multiple copies of IDOL Server or a component. It allows you to use failover, load balancing, or distributed content.

DIH (Distributed Index Handler)

DIH allows you to efficiently split and index extremely large quantities of data into multiple copies of IDOL Server or the Content component. DIH allows you to create a scalable solution that delivers high performance and high availability. It provides a flexible way to batch, route, and categorize the indexing of internal and external content into IDOL Server.

I**IDOL**

The Intelligent Data Operating Layer (IDOL) Server, which integrates unstructured, semi-structured and structured information from multiple repositories through an understanding of the content. It delivers a real-time environment in which operations across applications and content are automated.

IDOL Proxy component

An IDOL Server component that accepts incoming actions and distributes them to the appropriate subcomponent. IDOL Proxy also performs some maintenance operations to make sure that the subcomponents are running, and to start and stop them when necessary.

Import

Importing is the process where CFS, using KeyView, extracts metadata, content, and sub-files from items retrieved by a connector. CFS adds the information to documents so that it is indexed into IDOL Server. Importing allows IDOL server to use the information in a repository, without needing to process the information in its native format.

Ingest

Ingestion converts information that exists in a repository into documents that can be indexed into IDOL Server. Ingestion starts when a connector finds new documents in a repository, or documents that have been updated or deleted, and sends this information to CFS. Ingestion includes the import process, and processing tasks that can modify and enrich the information in a document.

Intellectual Asset Protection System (IAS)

An integrated security solution to protect your data. At the front end, authentication checks

that users are allowed to access the system that contains the result data. At the back end, entitlement checking and authentication combine to ensure that query results contain only documents that the user is allowed to see, from repositories that the user has permission to access. For more information, refer to the IDOL Document Security Administration Guide.

K**KeyView**

The IDOL component that extracts data, including text, metadata, and subfiles from over 1,000 different file types. KeyView can also convert documents to HTML format for viewing in a Web browser.

L**LDAP**

Lightweight Directory Access Protocol. Applications can use LDAP to retrieve information from a server. LDAP is used for directory services (such as corporate email and telephone directories) and user authentication. See also: active directory, primary domain controller.

License Server

License Server enables you to license and run multiple IDOL solutions. You must have a License Server on a machine with a known, static IP address.

O**OmniGroupServer (OGS)**

A server that manages access permissions for your users. It communicates with your repositories and IDOL Server to apply access permissions to documents.

P

primary domain controller

A server computer in a Microsoft Windows domain that controls various computer resources. See also: active directory, LDAP.

V

View

An IDOL component that converts files in a repository to HTML formats for viewing in a Web browser.

W

Wildcard

A character that stands in for any character or group of characters in a query.

X

XML

Extensible Markup Language. XML is a language that defines the different attributes of document content in a format that can be read by humans and machines. In IDOL Server, you can index documents in XML format. IDOL Server also returns action responses in XML format.

Send documentation feedback

If you have comments about this document, you can [contact the documentation team](#) by email. If an email client is configured on this system, click the link above and an email window opens with the following information in the subject line:

Feedback on Administration Guide (File System Connector 11.5)

Add your feedback to the email and click **Send**.

If no email client is available, copy the information above to a new message in a web mail client, and send your feedback to AutonomyTPFeedback@hpe.com.

We appreciate your feedback!
