Trademark notices

Adobe™ is a trademark of Adobe Systems Incorporated.

Microsoft® and Windows® are U.S. registered trademarks of Microsoft Corporation.

UNIX® is a registered trademark of The Open Group.

This product includes an interface of the 'zlib' general purpose compression library, which is Copyright © 1995-2002 Jean-loup Gailly and Mark Adler.

Documentation updates

The title page of this document contains the following identifying information:

- Software Version number, which indicates the software version.
- Document Release Date, which changes each time the document is updated.
- Software Release Date, which indicates the release date of this version of the software.

To check for recent software updates, go to https://downloads.autonomy.com/productDownloads.jsp.

To verify that you are using the most recent edition of a document, go to https://softwaresupport.hpe.com/group/softwaresupport/search-result?doctype=online help.

This site requires that you register for an HPE Passport and sign in. To register for an HPE Passport ID, go to https://hpp12.passport.hpe.com/hppcf/login.do.

You will also receive updated or new editions if you subscribe to the appropriate product support service. Contact your HPE sales representative for details.

Support

Visit the HPE Software Support Online web site at https://softwaresupport.hpe.com.

This web site provides contact information and details about the products, services, and support that HPE Software offers.

HPE Software online support provides customer self-solve capabilities. It provides a fast and efficient way to access interactive technical support tools needed to manage your business. As a valued support customer, you can benefit by using the support web site to:

- Search for knowledge documents of interest
- Submit and track support cases and enhancement requests
- Access product documentation
- Manage support contracts
- Look up HPE support contacts
- Review information about available services
- Enter into discussions with other software customers
- Research and register for software training

Most of the support areas require that you register as an HPE Passport user and sign in. Many also require a support contract.

To register for an HPE Passport ID, go to https://hpp12.passport.hpe.com/hppcf/login.do.

To find more information about access levels, go to https://softwaresupport.hpe.com/web/softwaresupport/access-levels.

To check for recent software updates, go to https://downloads.autonomy.com/productDownloads.jsp.

Contents

Part I: Overview of Filter SDK

This section provides an overview of the Filter SDK and describes how to use the .NET implementation of the API.

Chapter 1: Introducing Filter SDK

This section describes the Filter SDK package.

Overview

KeyView Filter SDK enables you to incorporate text extraction functionality into your own applications. It extracts text and metadata from a wide variety of file formats on numerous platforms, and can automatically recognize over 300 document types. It supports both file-based and stream-based I/O operations, and provides in-process or out-of-process filtering.

Filter SDK is part of the KeyView suite of products. KeyView provides high-speed text extraction, conversion to web-ready HTML and well-formed XML, and high-fidelity document viewing.

Features

- Document readers are threadsafe. The benefit of a threadsafe technology is that you can successfully extract text from hundreds of documents simultaneously. Documents are not queued for sequential filtering, but are actually filtered at the same time.
- Filter supports popular word processing, spreadsheet, and presentation formats. Body text, endnotes, footnotes, and additional items such as document metadata are all included as part of the filtering process.
- Sample programs are provided to demonstrate the functionality of the APIs.
- You can extract files embedded within files, such as email attachments or embedded OLE objects, by using the File Extraction API.
- You can configure memory management. If using the C API, you can provide your own memory allocator to the document readers.
- Filter allows for redirected input and output. You can provide an input stream that is not restricted to file system access.
- Filter automatically recognizes the file type being filtered and uses the appropriate filter. Your application does not need to rely on file name extensions to determine file types.
- You can filter documents to specific character encodings, such as Unicode or UTF-8.

- You can use Filter SDK in conjunction with other KeyView technologies, such as the Index, Highlight, and Annotate APIs.
- You can write custom document readers for formats not directly supported by KeyView.

Platforms, Compilers, and Dependencies

This section lists the supported platforms, supported compilers, and software dependencies for the KeyView software.

Supported Platforms

- CentOS 7
- FreeBSD 8.1 x86
- IBM AIX L6.1 PowerPC 32-bit and 64-bit
- IBM AIX L7.1 PowerPC 32-bit and 64-bit
- Mac OS X Mountain Lion 10.8 or higher on 32- and 64-bit Apple-Intel architecture
- Microsoft Windows Vista Business Edition x86 and x64. Other editions of Vista have not been tested, but are likely supported.
- Microsoft Windows 2008 Server Enterprise Edition x86 and x64
- Microsoft Windows 2008 Server R2
- Microsoft Windows 7 x86 and x64
- Microsoft Windows 8 x86 and x64
- Oracle Solaris 10 SPARC
- Oracle Solaris 10 x86 and x64
- Red Hat Enterprise Linux 5.0 x86 and x64
- Red Hat Enterprise Linux 6.0 x86 and x64
- SuSE Linux Enterprise Server 10, 10.1, 11, x86 and x64

Supported Compilers

Platform	Architecture	Compiler Name	Compiler Version
Microsoft Windows	x86	cl	Microsoft 32-bit C/C++ Optimizing Compiler Version 16.00.30319.01 for x86
	x64	cl	Microsoft C/C++ Optimizing Compiler Version 16.00.30319.01 for x64
Sun Solaris	x86 64-bit	Sun Studio 12	Sun C 5.9 SunOS_i386 Patch 124868-01 2007/07/12
	SPARC 64-bit	Sun Studio	Sun C 5.8 Patch 121015-06 2007/10/03

Platform	Architecture	Compiler Name	Compiler Version
		11	
Linux	x86	gcc / g++	3.4.3 (Redhat 4), 4.1.0 (SuSE Linux 10)
	x64	gcc / g++	4.1.0 (Redhat 4), 4.1.0 (SuSE Linux 10)
IBM AIX	Power	xlC_r / cc_r	IBM XL C/C++ Enterprise Edition V8.0
Mac OSX	Apple-Intel 32-bit and 64-bit	LLVM	Apple LLVM 5.1 (clang-503.0.40) (based on LLVM 3.4svn)
FreeBSD	BSD x86	gcc / g++	4.2.1 [FreeBSD] 20070719

Supported Compilers for Java and .NET Components

Component	Compiler
Java components	Java 1.5
.NET components	Microsoft Visual J# 2005 Compiler 8.00.50727.42

Software Dependencies

Some KeyView components require specific third-party software:

- Java Runtime Environment (JRE) or Java Software Developer Kit (JDK) version 1.5 is required for Java API and graphics conversion in Export SDK.
- Outlook 2002 client or later versions is required when processing Microsoft Outlook Personal Folders (PST) files using the MAPI-based reader (`pstsr`). The native PST reader (`pstnsr`) does not require an Outlook client.

  > **NOTE:**
  > If you are using 32-bit KeyView, you must install 32-bit Outlook. If you are using 64-bit KeyView, you must install 64-bit Outlook.
  >
  > If the bit editions do not match, an error message from Microsoft Office Outlook is displayed:
  >
  > ```
  > Either there is a no default mail client or the current mail client cannot
  > fulfill the messaging request. Please run Microsoft Outlook and set it as
  > the default mail client.
  > ```
  >
  > Additionally, KeyView displays the following return code:
  >
  > ```
  > Error 32: KVError_PSTAccessFailed.
  > ```

- Lotus Notes or Lotus Domino is required for Lotus Notes database (NSF) file processing. The minimum requirement is 6.5.1, but version 8.5 is recommended.

- Microsoft .NET Framework SDK version 2.0, Microsoft .NET Framework version 2.0 Redistributable Package is required if you are programming in a .NET environment.
- Microsoft Visual C++ 2013 and Microsoft Visual C++ 2010 Redistributables (Windows only).

Windows Installation

To install the SDK on Windows, use the following procedure.

To install the SDK

1. Run the installation program, `KeyView`*`ProductName`*`SDK_`*`VersionNumber_OS`*`.exe`, where *`ProductName`* is the name of the product, *`VersionNumber`* is the product version number, and *`OS`* is the operating system.

   For example:

   ```
   KeyViewFilterSDK_11.5_Windows_X86_64.exe
   ```

   The installation wizard opens.
2. Read the instructions and click **Next**.

   The License Agreement page opens.
3. Read the agreement. If you agree to the terms, click **I accept the agreement**, and then click **Next**.

   The Installation Directory page opens.
4. Select the directory in which to install the SDK. To specify a directory other than the default, click  , and then specify another directory. After choosing where to install the SDK, click **Next**.

   The License Key page opens.
5. Type the company name and license key that were provided when you purchased KeyView, and then click **Next**.
   - The company name is case sensitive.
   - The license key is a string that contains 31 characters.

   > **NOTE:**
   > The installation program validates the company name and license key and generates the file *`install`*`\`*`OS`*`\bin\kv.lic` (where *`install`* is your chosen installation folder and *`OS`* is the name of the operating system platform). The license information is validated when the KeyView API is used. If you do not enter a license key at this step, or if you enter invalid information, the KeyView SDK is installed, but the API does not function. When you obtain a valid license key, you can either re-install the KeyView SDK, or manually update the license key file (`kv.lic`) with the new information. For more information, see License Information, on page 17.

   The Pre-Installation Summary dialog box opens.
6. Review the settings, and then click **Next**.

   The SDK is installed.
7. Click **Finish**.

UNIX Installation

To install the SDK, use one of the following procedures.

To install the SDK from the graphical interface

- Run the installation program and follow the on-screen instructions.

To install the SDK from the console

1. Run the installation program from the console as follows:

   `./KeyViewFilterSDK_`*`VersionNumber_Platform`*`.exe --mode text`

   where:

`VersionNumber`	is the product version.
`Platform`	is the name of the platform.

2. Read the welcome message and instructions and press `Enter`.

   The first page of the license agreement is displayed.

3. Read the license information, pressing `Enter` to continue through the text. After you finish reading the text, and if you accept the agreement, type **`Y`** and press `Enter`.

   You are asked to choose an installation folder.

4. Type an absolute path or press `Enter` to accept the default location.

   You are asked for license information.

5. At the **Company Name** prompt, type the company name that was provided when you purchased KeyView, and then press `Enter`. The company name is case sensitive.

6. At the **License Key** prompt, type the license key that was provided when you purchased KeyView, and then press `Enter`. The license key is a string that contains 31 characters.

   > **NOTE:**
   > The installation program generates the file *`install`*`\`*`OS`*`\bin\kv.lic` (where *`install`* is your chosen installation folder and *`OS`* is the name of the operating system platform). The license information is validated when the KeyView API is used. If you do not enter a license key at this step, or if you enter invalid information, the KeyView SDK is installed but the API does not function. When you obtain a valid license key, you can either re-install the KeyView SDK, or manually update the license key file (`kv.lic`) with the new information. For more information, see License Information, on the next page.

   The Pre-Installation summary is displayed.

7. If you are satisfied with the information displayed in the summary, press `Enter`.

   The SDK is installed.

Package Contents

The Filter SDK installation contains:

- All the libraries and executables necessary for extracting text from a wide variety of formats.
- The include files that define the functions and structures used by the application to establish an interface with Filter:

adapi.h	kvfilter.h
adinfo.h	kvioobj.h
kvcfsr.h	kvtoken.h
kvxtract.h	kvtypes.h
kvfilt.h	kvxtract.h
kvfilt2.h	kwautdef.h

- The Java API implemented in the package `com.verity.api.filter` contained in the file `KeyView.jar`.
- The .NET API implemented in the namespace `Autonomy.API.Filter` in the library `FilterDotNet.dll`.
- The C++ SDK, which can be found in the `cppapi` folder.
- Sample programs that demonstrate File Extraction and Filter functionality using the APIs.
- The files necessary to create a custom document reader, and the source for a sample document reader for UTF-8. See Develop a Custom Reader, on page 197.

License Information

During installation, the installation program validates the organization name and license key that you enter, and generates the *install*`/`*OS*`/bin/kv.lic` file, where *install* is the directory in which you installed KeyView, and *OS* is the operating system. This file is opened and validated when the KeyView API is used.

The `kv.lic` file contains the organization name and the 31-digit license key you specified during installation. The contents of a `kv.lic` file looks similar to the following:

```
Company Name
XXXXXXX-XXXXXXX-XXXXXXX-XXXXXXX
```

The license key controls whether the following are enabled:

- the full version of the KeyView SDK
- the trial version of the KeyView SDK
- language detection and advanced document readers—The following components are considered advanced features, and are licensed separately:

- Microsoft Outlook Personal Folders (PST) reader (`pstsr` and `pstnsr`)
- Lotus Notes database (NSF) reader (`nsfsr`)
- Mailbox (MBX) reader (`mbxsr`)
- Character set detection library (`kvlangdetect`)

If you change the license key at any time, you must update the licensing information in the `kv.lic` file. See Update License Information.

Enable Advanced Document Readers

To enable advanced readers in one of the KeyView SDKs, you must obtain an appropriate license key from HPE and update the installed license key with the new information as described in Update License Information.

If you are enabling the MBX reader in an existing installation of Filter, in addition to updating the license key, change the parameter `208=eml` to `208=mbx` in the `formats.ini` file.

Update License Information

If you currently have an evaluation version of KeyView and have purchased a full version of the SDK, or you are adding a document reader (for example, the PST reader), you must update the license information that was installed with the original version of the KeyView SDK.

If you installed a full version of KeyView, but did not enter licensing information at the time of installation, you must also update the license information.

To update the information, do one of the following:

- Manually update the license information that is stored in the text file named `kv.lic`.
- Re-install the product and enter the new license information when prompted.

To update the KeyView license information

1. Open the license key file, `kv.lic`, in a text editor. The file is in the *`install`*`\`*`OS`*`\bin` directory, where *`install`* is the directory in which you installed KeyView, and *`OS`* is the operating system. The file contains the following text:

   ```
   COMPANY NAME
   XXXXXXX-XXXXXXX-XXXXXXX-XXXXXXX
   ```

2. Replace the text *`COMPANY NAME`* with the company name that appears at the top of the License Key Sheet provided by HPE. Enter the text exactly as it appears in the document.
3. Replace the characters *`XXXXXX-XXXXXXX-XXXXXXX-XXXXXXX`* with the appropriate license key from the License Key Sheet provided by HPE. The license key is listed in the **Key** column in the **Standalone Products** table. The key is a string that contains 31 characters, for example, `2TQD22D-2M6FV66-2KPF23S-2GEM5AB`. Enter the characters exactly as they appear in the document, including the dashes, but do not include a leading or trailing space.
4. The finished `kv.lic` file looks similar to the following:

   ```
   Autonomy
   ```

```
24QD22D-2M6FV66-2KPF23S-2G8M59B
```

5. Save the `kv.lic` file.

Directory Structure

The following table describes the directories created during the Filter SDK installation. The variable *install* is the path name of the Filter installation directory (for example, `/usr/autonomy/KeyviewFilterSDK` on UNIX, or `C:\Program Files\Autonomy\KeyviewFilterSDK` on Windows).

The variable *OS* is the operating system for which the SDK is installed. For example, the `bin` directory on a standard 32-bit Windows installation would be located at `C:\Program Files\Autonomy\KeyviewFilterSDK\WINDOWS\bin`.

Installed directory structure

Directory	Description
*install**OS*\bin	Contains the libraries, the format detection file `formats.ini`, the license key file `kv.lic`, and other supporting files.
*install**OS*\lib	(Solaris installations only) Contains the redistributable `libstlport.so.1` library, which is required to run KeyView on Solaris platforms.
install\dotnetapi	Contains the source files for the .NET API.
install\dotnetapi\dotnethelp	Contains the help for the .NET API.
install\dotnetapi\sample	Contains the sample programs for the .NET API.
install\cppapi	Contains the source files for the C++ API.
install\cppapi\sample	Contains the sample programs for the C++ API.
install\guide	Contains the KeyView Filter SDK programming guides in PDF and HTML format.
install\include	Contains the header files required for Filter.
install\javaapi\javadoc	Contains the Javadoc for the Java API.
install\javaapi\sample	Contains the source files and sample programs for the Java API.
install\rel_notes	Contains the *KeyView Filter SDK Release Notes* in PDF format.
install\samples\filter	Contains a sample program demonstrating the Filter interface for the C API.

Installed directory structure, continued

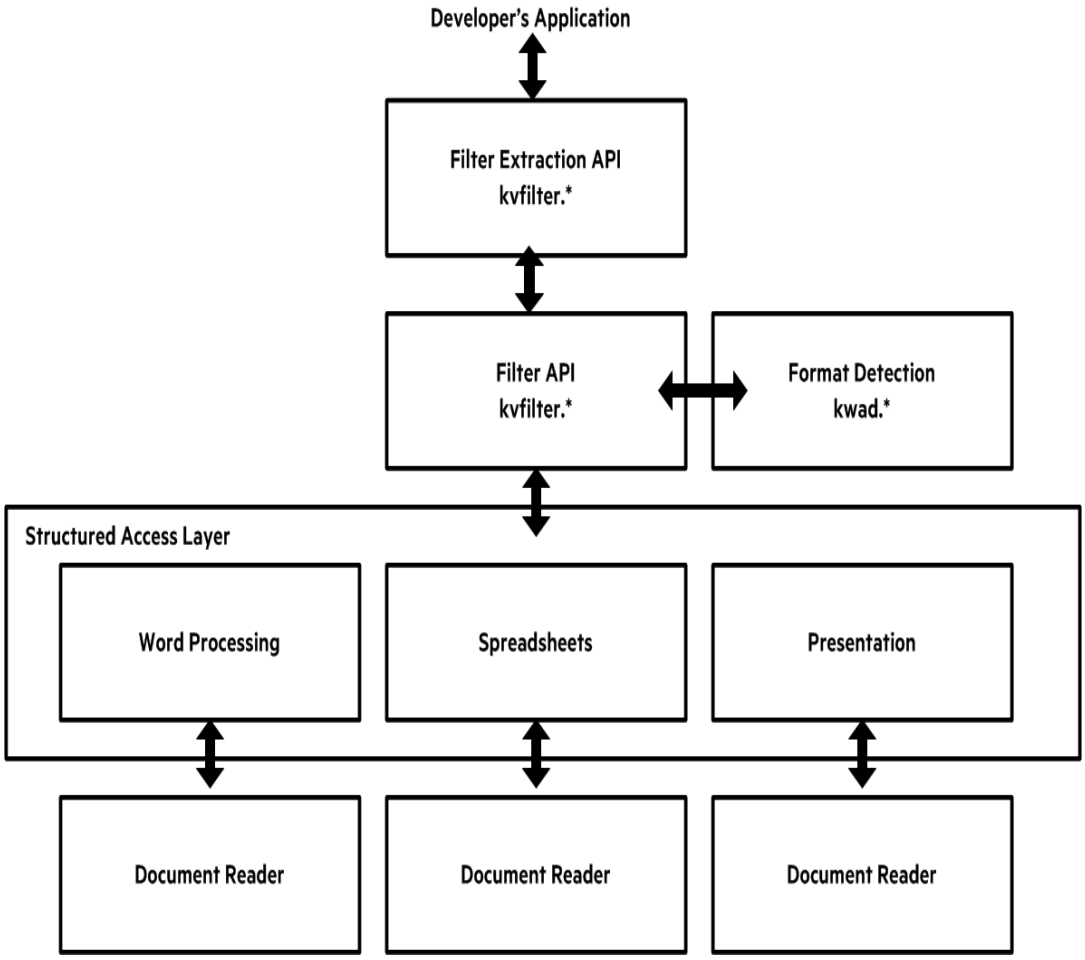
Directory	Description
install\samples\filterca	Contains a C sample program demonstrating extraction of a content access stream.
install\samples\pdfini	Contains the initialization file used to extract custom metadata from PDF documents.
install\samples\tstxtract	Contains a C sample program demonstrating the File Extraction interface.
install\samples\utf8sr	Contains the source for the sample document reader for UTF-8 files. You can use this to create your own custom document readers.
install\samples\utf8sr\bin	Contains the C program `filtertest`. You can use this program to test your custom document readers. See Develop a Custom Reader, on page 197.

Chapter 2: Getting Started

This section provides an overview of Filter SDK, and describes how to use the .NET implementation of the API.

Architectural Overview

The general architecture of the KeyView Filter technology is the same across all supported platforms and is illustrated in the following diagram:



Each component is described in the following table.

Architectural Components

Component	Description
Developer's Application	The developer's application interfaces directly with the Filter API through either a C-language, Java or .NET implementation.
File Extraction API	The File Extraction API opens a file and extracts the file's subfiles so they are exposed for filtering. See Use the File Extraction API, on page 33.
Filter API	The Filter API exposes the filtering functionality and controls all other modules during the filtering process. See Use the Filter API, on page 55.
Format Detection	This module determines the file type of the input stream, allowing the Filter API to return that information to the developer's application, or to load the appropriate structured access layer for further processing. See File Format Detection, on page 166 for more information format detection.
Structured	There are three modules that reside in the structured access layer—one each for word

Architectural Components, continued

Component	Description
Access Layer	metadata retrieval.
Document Readers	Each document reader reads a specific file format and sends a text stream of the document to the structured access layer. Each filter is loaded as required by the structured access layer. See Document Readers, on page 190 for a complete list of document readers.

Enhance Performance

KeyView is designed for optimal performance out of the box. However, there are some parameters that you can adjust to improve system performance according to your needs.

File Caching

To reduce the frequency of I/O operations, and consequently improve performance, the KeyView readers load file data into memory. The readers then read the data from the cache rather than the physical disk. You can configure the amount of memory used for file caching through the `formats.ini` file. Generally, when you increase the memory, performance will improve.

By default, KeyView uses a maximum of 1MB of memory for each thread. If the file data is larger than 1MB, up to 1MB of data is cached and the data beyond 1MB is read from disk. The minimum amount of memory that can be used for file caching is 64KB.

To determine a reasonable value, divide the maximum amount of memory you want KeyView to use for file caching by the total number of threads. For example, if you want KeyView to use a maximum of 50MB of memory and have 10 threads, set the value to 5MB.

To modify the memory allocated for file caching, change the value for the following parameter in the `[DiskCache]` section of the `formats.ini` file:

```
DiskCacheSize=1024
```

The value is in kilobytes. If this parameter is not set or is set to 0 (zero), the minimum value of 64KB is used.

The `formats.ini` file is in the directory `install\`*`OS`*`\bin`, where `install` is the path name of the KeyView installation directory and `OS` is the name of the operating system.

Filtering

Filter SDK enables you to *filter* many different types of documents. Filtering is the process of extracting the text from a document without the application-specific markup. However, the filtering process can also include the following:

- Subfile extraction—exposes all subfiles for filtering. See Use the File Extraction API, on page 33.
- File format extraction—detects a file's format, and reports the information to the API, which in turn reports the information to the developer's application. See File Format Detection, on page 166.
- Metadata extraction—extracts selected metadata (document properties) from a file. See Extract Metadata, on page 58.
- Character set conversion—controls the character set of both the input and the output text. See Convert Character Sets, on page 61.

Subfile Extraction

To filter a file, you must first determine whether the file contains any subfiles (attachments, embedded OLE objects, and so on). A file that contains subfiles is called a *container* file. Archive files (such as ZIP), mail messages with attachments (such as Microsoft Outlook Express), mail stores (such as Microsoft Outlook Personal Folders), and compound documents with embedded OLE objects (such as a Microsoft Word document with an embedded Excel chart) are examples of container files.

If the file is a container file, the container must be opened and its subfiles extracted using the File Extraction interface. The extraction process is done repeatedly until all subfiles are extracted and exposed for filtering. Once a subfile is extracted, you can use the Filter API to filter the file.

If a file is not a container, you should pass it directly to the Filter API for filtering without extraction.

The `TestExtract` sample program demonstrates this logic for extracting and filtering files. See TestExtract, on page 78 for more information.

Use the .NET Implementation of the API

The .NET version of the Filter API provides an interface to the core functionality of the C API. It contains one primary class (`Filter`) that wraps the filter functionality of the C API. It is implemented in the namespace `Autonomy.API.Filter` contained in the file `FilterDotNet.dll`. The library is in the directory *`install`*`\`*`OS`*`\bin`, where *`install`* is the path name of the Filter installation directory and *`OS`* is the name of the operating system.

For more information on the .NET API, see the .NET help file `FilterDotNetHelp.chm` in the directory *`install`*`\dotnetapi\dotnethelp`.

Input/Output Operations

In the Filter .NET API, input and output can be either a physical file accessed through a file path, or a .NET stream. Depending on the method signature you use, you can create the following filtering

processes:

- filter an input file to output file
- filter an input file to an output stream
- filter an input stream to an output stream
- filter an input stream to an output file
- filter an input file and return one chunk of data at a time
- filter an input stream and return one chunk of data at a time

Many methods in the .NET API have method signatures supporting one or more of these filtering processes. When you select a method, make sure that you use the correct signature for the desired input and output type.

The input source can be set by calling the `SetInputSource` method, or prior to using the `DoFilter`, `CanFilter`, `CanFilterEx`, `GetDocFormatInfo`, or `GetSummaryInfo` methods. The latter methods take the input source as one of their parameters.

> **NOTE:**
> When the input source is from a .NET stream, Filter creates an internal buffer from the stream. If the input is a large file, HPE recommends that you use a file as the input source.

Filter in File or Stream Mode

To filter files using the methods in the `Filter` class

1. Instantiate a `Filter` object using either the default constructor or the constructor that sets the output character set and filter flags:
   a. Use the default constructor `Filter()`. For example:

   ```
   objFilter = new Filter();
   ```

   b. Use the constructor `Filter(string OutputCharSet, UInt32 filterFlags)`. For example:

   ```
   objFilter = new Filter(outputCharSet,
   FilterConstant.FilterFlagConstant.FILTERFLAG_OOPLOGON);
   ```

   The Filter flags provide instructions on how to process a file or stream. For example, they specify whether an error log is generated during filtering (`FILTERFLAG_OOPLOGON`) or whether headers and footers are extracted from the document (`FILTERFLAG_HEADERFOOTERTAGS`).

   > **NOTE:**
   > Filter runs out of process by default. See The Filter Process Model, on the next page for more information.

2. Set the location of the Filter libraries by using the `FilterDirectory` property. These libraries are normally stored in the directory `install\`*`OS`*`\bin`, where `install` is the path name of the Filter installation directory and `OS` is the name of the operating system. For example:

   ```
   objFilter.FilterDirectory = filterDir;
   ```

3. Set the input source as either a file or input stream by calling the `SetInputSource` method.

```
objFilter.SetInputSource(m_inFile);
```

4. Filter the file or stream by calling either the `FilterTo` or `DoFilterChunk` method. The `FilterTo` method extracts the data to a file or a stream. The `DoFilterChunk` method extracts one chunk of data from a file or a stream. It must be called repeatedly the until entire buffer is filtered.

   If filtering in file mode, use the following code:

   ```
   {
     m_objFilter.filterTo(m_extractDir + filename + m_extension);
   }
   ```

   If filtering in stream mode, use the following code:

   ```
    {
     outf = new File(m_extractDir + filename + m_extension);
     fos = new FileOutputStream(outf);
     m_objFilter.filterTo(fos);
     fos.close();
    }
   ```

5. Terminate the filtering session and free allocated system resources by calling the `ShutdownFilter()` method. This must be called within a `Finally` block.

   ```
   m_objFilter.ShutdownFilter();
   ```

Multithreaded Filtering

To ensure multithreaded filter processes are thread-safe, you must create a unique Filter context for every thread by instantiating a `Filter` object. In addition, threads must not share context objects, and the same context object must be used for all API calls in the same thread. Creating a context object for every thread does not affect performance because the context object uses minimal resources.

For example, your code should have the following logic in a thread:

```
objFilter = new Filter();
objFilter.FilterDirectory = m_filterDirectory;
objFilter.SetInputSource(infile);
objFilter.GetDocFormatInfo();

if (objFilter.CanFilter() == true)

objFilter.FilterTo(outfile);

objFilter.ShutdownFilter();
```

The Filter Process Model

By default, Filter runs independently from the calling application process. This is called *out-of-process* filtering. Out-of-process filtering protects the stability of the calling application in the rare case when a malformed document causes Filter to fail. You can configure Filter to run in the same process as the

filtering. However, it is strongly recommended you run Filter out of process whenever possible.

With the exception of Solaris and AIX, the creation of child processes on UNIX adheres to Portable Operating System Interface (POSIX) standards. Solaris and AIX use thread semantics. If required, a version of `kvfilter` with POSIX thread semantics is available for Solaris and AIX. For Solaris, the file is `kvfilter_posix.so`. For AIX, the file is `kvfilter_nsl.a`. These files must be renamed `kvfilter.so` or `kvfilter.a` to be used by Filter.

To monitor and debug filtering operations during out-of-process filtering, you can generate an error log at run time. See Generate an Error Log, on page 55.

The following methods run in process or out of process:

Filter API

- CanFilter
- CanFilterEx
- DoFilter
- DoFilterChunk
- GetSummaryInfo
- GetDocFormatInfo

File Extraction API

- ExtractCloseDocument
- ExtractGetSubFileInfo
- ExtractGetSubFileMetadata
- ExtractSubFile
- ExtractGetMainFileInfo
- ExtractOpenDocument
- GetSummaryInfo

Other Filter API methods always run in process.

Persist the Child Process

By default, in out-of-process filtering, the parent process maintains a persistent connection with the child server after each file is filtered. When the connection is preserved in this way, subsequent filtering requests are processed more quickly because the server is already prepared to receive data.

You can restart the server at regular intervals by using a method or a configuration setting.

In the API

To force KeyView to restart, call the `refreshFilterKVOOP()` method.

```
public void refreshFilterKVOOP();
```

In the formats.ini File

To control whether Filter persists the server, use the `kvoopRefresh` parameter in the `[FilterSDK_Config]` section of the `formats.ini` file:

`kvoopRefresh=0`	When this is set to 0 (zero), the connection to the server is persisted for as long as the parent process is running or until the server fails. This is the default.
`kvoopRefresh=n`	When this is set to `n`, the connection is persisted for `n` filter requests. After the `n`th request, the server is shutdown and restarted before processing the next request. For example, if `kvooprefresh=5`, the connection to the server is persisted for 5 filter requests. For the 6th request, the server is shutdown and restarted.

To control whether the parent process attempts to filter a file after the file has caused the server to fail, use the `kvoopRetry` parameter in the `[FilterSDK_Config]` section of the `formats.ini` file:

`kvoopRetry=0`	When this option is set to **`0`** and the server fails, the parent process does not resend the file to a new server.
`kvoopRetry=n`	When this option is set to *n* (a positive number) and the server fails, the parent process resends the file to a new server *n* times. By default, the `kvoopRetry` is set to **`1`**, and the file is resent to a server once.

The `formats.ini` file is in the directory `install\`*`OS`*`\bin`, where `install` is the path name of the Filter installation directory and `OS` is the name of the operating system.

> **NOTE:**
> The `kvoopRefresh` and `kvoopRetry` parameters do no apply when running the File Extraction functions out of process. See Run File Extraction Functions Out of Process, on the next page.

Run Filter In Process

By default, Filter runs out of process. However, you can enable in-process filtering through the API or in the `formats.ini` file. If the type of process is not specified in the `formats.ini` or in the API, then Filter is run out of process. If the type of process is specified in the `formats.ini` *and* in the API, the setting in the API takes precedence.

In the API

To run Filter in process, instantiate the Filter object using the constructor `Filter(string OutputCharSet, UInt32 filterFlags)`, and set the `FilterFlags` argument to `FILTERFLAG_INPROCESS`.

```
objFilter = new Filter(outputCharSet,
FilterConstant.FilterFlagsConstant.FILTERFLAG_INPROCESS);
```

In the formats.ini File

To run Filter in process, set the following parameter in the `[FilterSDK_Config]` section of the `formats.ini` file to 1:

```
default_inprocess=1
```

By default this is set to 0 (zero), which enables out-of-process filtering.

The `formats.ini` file is in the directory `install\OS\bin`, where `install` is the path name of the Filter installation directory and `OS` is the name of the operating system.

Run File Extraction Functions Out of Process

The out-of-process setting specified when you create the Filter object or in the `formats.ini` is automatically propagated to the File Extraction API. When you extract subfiles from container files and pass the files for filtering out of process, Filter generates a server called `kvoop.exe` for filtering and a duplicate server also called `kvoop.exe` for file extraction. These servers are independent, so if the filtering service stops responding, the file extraction service can continue extracting files uninterrupted.

Restart the File Extraction Server

If the file extraction server fails on a file and throws the exception `KVError_InvalidOopDriverSignature` or `KVError_InvalidOopServiceSignature`, you must restart the server by recreating the Filter object, and process the source file again.

Out-of-Process Logging

Logging is available for out-of-process filtering. The `kvoop` server can now create a log file that captures information on the files being processed, storing one entry per process. The generated log file is called `xxxx_kvoop.log`, where `xxxx` is a unique number identifying the process.

In the rare case when the `kvoop` server fails, you can use the log files to determine which file caused the failure. After processing is complete and the system shuts down, the logs are automatically deleted. To keep the log files after processing is successfully completed, see Keep Log Files, on page 31.

> **NOTE:**
> Out-of-process logging is not supported on AIX.

Enable Out-of-Process Logging

To enable out-of-process logging, set the `KVOOP_LOGS_DIR` environment variable to the directory in which you want the log files to be stored. By default, logging is not enabled.

On UNIX, the variable is set as follows:

```
setenv KVOOP_LOGS_DIR /tmp
```

On Windows, the variable is set as follows:

```
set KVOOP_LOGS_DIR=c:\tmp
```

The following log file is created in the directory:

*process_id*_kvoop.log

where *process_id* is a numeric value representing the logged process. New messages are appended to the file, and truncation is disabled by default.

If KeyView terminates unexpectedly and Windows minidump is enabled, a *process_id*_crash_info.txt file is generated (see Enable Windows Minidump, below). If logging was not been enabled at the time of termination, this file contains instructions on how to enable logging.

Set the Verbosity Level

You can control how much information is written to the file by setting the KVOOP_LOG_VERBOSITY environment variable. For example:

```
set KVOOP_LOG_VERBOSITY=1
```

The variable can be set to the following:

1 Include only error messages.

2 Include errors and warnings.

3 Include errors, warnings, and general information. This is the default.

4 Include all possible information. This setting is useful for debugging purposes.

Enable Windows Minidump

KeyView can use the Windows minidump feature to provide additional logging information, which can be useful for debugging purposes.

The Windows minidump is disabled by default. To enable the Windows minidump, set KVOOP_DUMP_ENABLE to **1**. If an unexpected termination occurs after the minidump is enabled, three files are generated:

***process_id*_crash_info.txt**. Contains KVOOP state and runtime information at the time of termination. If logging was not enabled at the time of termination, this file contains instructions on how to enable logging.

***process_id*_process_list.txt**. Contains information from the DLLs that were loaded at the time of the termination.

***process_id*_report.dmp**. This is the Windows dump file, which contains further information about the termination. You can open it with either a Windows debugger or autnhelper.exe (this file must be copied to the same directory).

You can control the amount of information presented in the Windows dump file by creating the following files in the directory:

```
dumper.NORMAL
dumper.WITHDATASEGS
```

```
dumper.WITHFULLMEMORY
dumper.WITHHANDLEDATA
```

Keep Log Files

After processing is complete and the system is shut down, the log files are automatically deleted from the directory. To keep the log files after a successful run, set the `KVOOP_KEEP_LOGS` environment variable.

On UNIX, set the variable as follows:

```
setenv KVOOP_KEEP_LOGS 1
```

On Windows, set the variable as follows:

```
set KVOOP_KEEP_LOGS=1
```

Run File Detection In or Out of Process

By default, detection runs in out-of-process mode. However, you can enable in-process detection through the API or in the `formats.ini` file. If the type of process is not specified in the `formats.ini` or in the API, detection runs in out-of-process mode. If the type of process is specified in the `formats.ini` *and* in the API, the setting in the API takes precedence.

Specify the Process Type In the formats.ini File

Add the `default_detect_inprocess` flag to a `[FilterSDK_Config]` section in the `formats.ini` file to control the default behavior for detection. Set the flag to **`0`** for out-of-process detection, and **`1`** for in-process detection. For example,

```
[FilterSDK Config]
default_detect_inprocess=0
```

If this flag is not specified, the file detection behavior is determined by the `default_inprocess` flag for filtering. For example, if you set `default_inprocess` to **`1`**, filtering and file detection runs in in-process mode by default; if you set `default_inprocess` to **`0`**, filtering and file detection runs in out-of-process mode by default.

If you set both the `default_inprocess` and `default_detect_inprocess` flags, `default_inprocess` controls the default filtering behavior and `default_detect_inprocess` controls the default file detection behavior.

Specify the Process Type In the API

To run Filter in process, instantiate the Filter object by using the constructor `Filter(string OutputCharSet, UInt32 filterFlags)`, and set the `FilterFlags` argument to **`FILTERFLAG_DETECTINPROCESS`**. To run detection in out-of-process mode, set `FILTERFLAG_DETECTOUTOFPROCESS`.

```
objFilter = new Filter(outputCharSet,
FilterConstant.FilterFlagsConstant.FILTERFLAG_DETECTINPROCESS);
```

Part II: Use Filter SDK

This section explains how to perform some basic tasks by using the File Extraction and Filter APIs, and describes the sample programs.

Chapter 3: Use the File Extraction API

This section describes how to extract subfiles from a container file using the File Extraction API.

Introduction

To filter a file, you must first determine whether the file contains any subfiles (attachments, embedded OLE objects, and so on). A file that contains subfiles is called a *container* file. A container file has a main file (parent) and subfiles (children) embedded in the main file. The following are examples of container files:

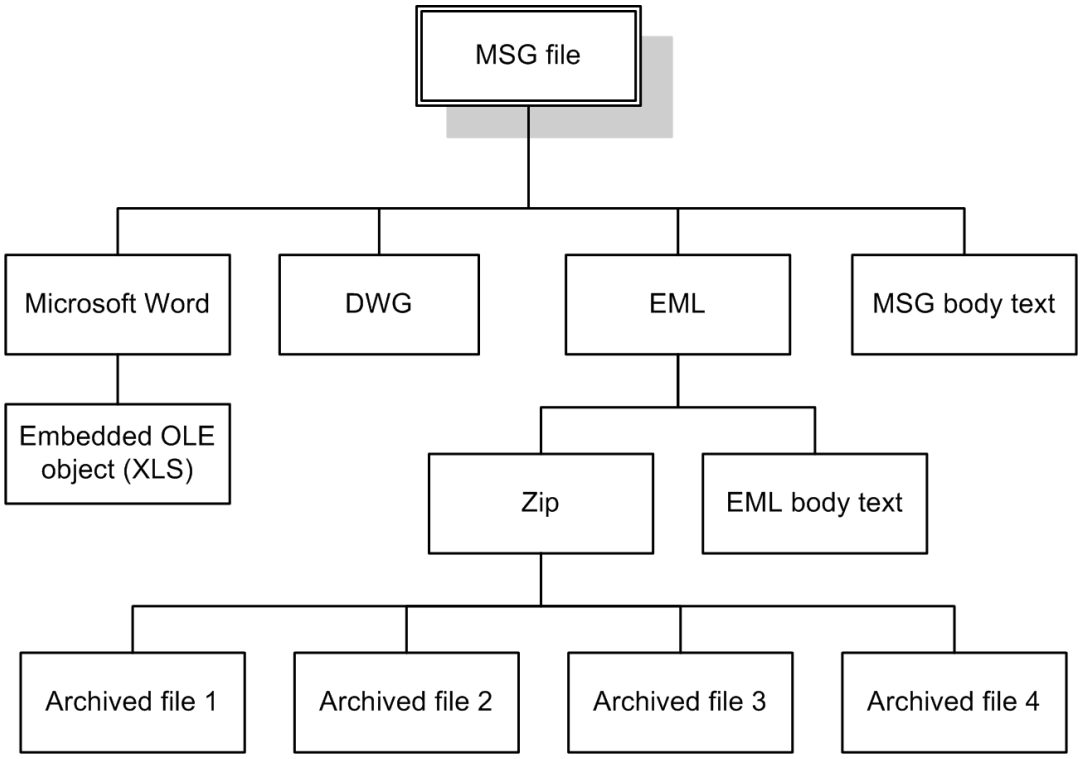
- Archive files such as ZIP, TAR, and RAR.
- Mail messages such as Outlook (MSG) and Outlook Express (EML).
- Mail stores such as Microsoft Outlook Personal Folders (PST), Mailbox (MBX), and Lotus Notes database (NSF).
- PDF files that contain file attachments.
- Compound documents with embedded OLE objects such as a Microsoft Word document with an embedded Excel chart.

> **NOTE:**
> Supported Formats, on page 84 indicates which formats are treated as container files and which are supported by the File Extraction API.

The subfiles might also be container files, creating a file hierarchy of multiple levels. For example, let us say an MSG file (the root parent) contains three attachments:

- a Microsoft Word document that contains an embedded Microsoft Excel spreadsheet.
- an AutoCAD drawing file (DWG).
- an EML file with an attached Zip file, which in turn contains four archived files.

The following diagram shows the file's hierarchy.



NOTE:
The parent MSG file contains four first-level children. The body text of a message file, although not a standalone file in the container, is considered a child of the parent file.

Extract Subfiles

To filter all files in a container file, you must open the container and extract its subfiles to either a file or a stream by using the *File Extraction API*. The extraction process is done repeatedly until all subfiles are extracted and exposed for filtering. After a subfile is extracted, you can call Filter API methods to filter the data.

If you want to filter a container file and its subfiles, to a single file, you must extract all files from the container, filter the files, and then append each filtered output file to its parent.

To extract subfiles

1. Open the source file by calling the `ExtractOpenDocument` method. This call defines the parameters necessary to open a file for extraction.

2. Determine whether the main file is a container file (contains subfiles) by calling the `ExtractGetMainFileInfo()` method.
3. If the call to `ExtractGetMainFileInfo()` determined the source file is a container file, proceed to step 4; otherwise, filter the file.
4. Determine whether the subfile is itself a container (contains subfiles) by calling the `ExtractGetSubFileInfo` method.
5. Extract the subfile by calling the `ExtractSubFile` method.
6. If the call to `ExtractGetSubFileInfo` determined the subfile is a container file, repeat step 1 through step 5 until all subfiles are extracted and the lowest level of subfiles is reached; otherwise, filter the file.

Extract Images

You can use the File Extraction API to extract images within the file by specifying the following in the `formats.ini` file:

```
[Options]
ExtractImages=TRUE
```

If you set this option, images within the file behave in the same way as any other subfile. Extracted images have the name `image[X].[Y]`, where `[X]` is an integer, and `[Y]` is the extension. The format of the image is the same as the format in which it is stored in the document.

This option can also be enabled by passing `KVFLT_EXTRACTIMAGES` to the `fpFilterConfig` function.

Recreate a File's Hierarchy

When a container file is extracted, any relationships between the subfiles in the container are not maintained. However, the File Extraction interface provides information that enables you to recreate the hierarchy. The hierarchy can be used to create a directory structure in a file system, or to categorize documents according to their relationship to each other. For example, if you use KeyView to generate text for a search engine, the hierarchical information enables your users to search for a document based on the document's parent or sibling. In addition, when the document is returned to the user, the parent and sibling documents can be returned as recommendations.

The information needed to recreate a file's hierarchy is provided in the call to `ExtractGetSubFileInfo`. Call this method to retrieve an object of `ExtractSubFileInfo`, then use the `ParentIndex` and `ChildArray()` properties in this object to retrieve information about the subfile's parent and children. Since you can only retrieve the first-level children in a subfile, you must call `ExtractGetSubFileInfo` repeatedly until information for the leaf-node children is extracted.

Create a Root Node

Because of their structure, some container files do not contain a subfile or folder which acts as a root directory on which the hierarchy can be based. For example, subfiles in a Zip archive can be extracted, but none of the subfiles represent the root of the hierarchy. In this case, an artificial *root node* must be created at the top of the file hierarchy as a point of reference for each child, and ultimately to recreate

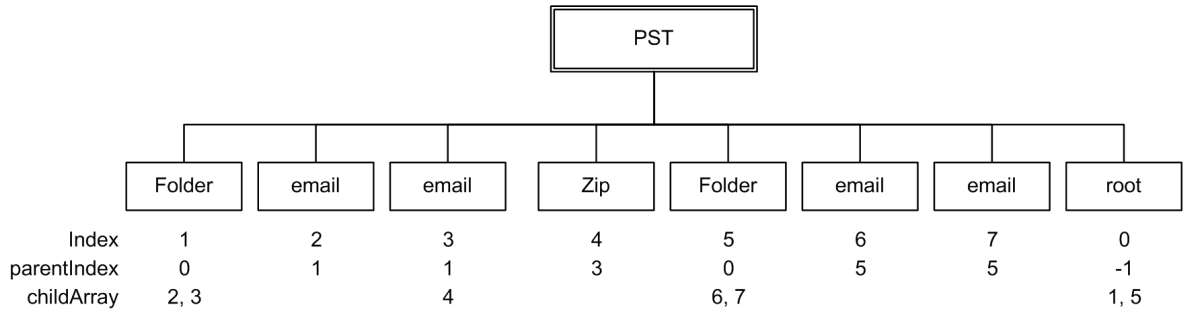
the relationships. This artificial root node is an internal object, and is extracted to disk as a directory called `root`. Its index number is 0.

To create a root node, set the `CreateRootNode` property in the `ExtractOpenDocConfig` contructor, and pass `ExtractOpenDocConfig` to the `ExtractOpenDocument` method. When a root node is created, the value returned from the `NumSubFiles` property in the `ExtractMainFileInfo` constructor includes the root node. For example, when you call `ExtractGetMainFileInfo` on a Microsoft Word document with three embedded OLE objects and the root node is disabled, the number of subfiles is 3. If you create a root node, the number of subfiles is 4.

Example

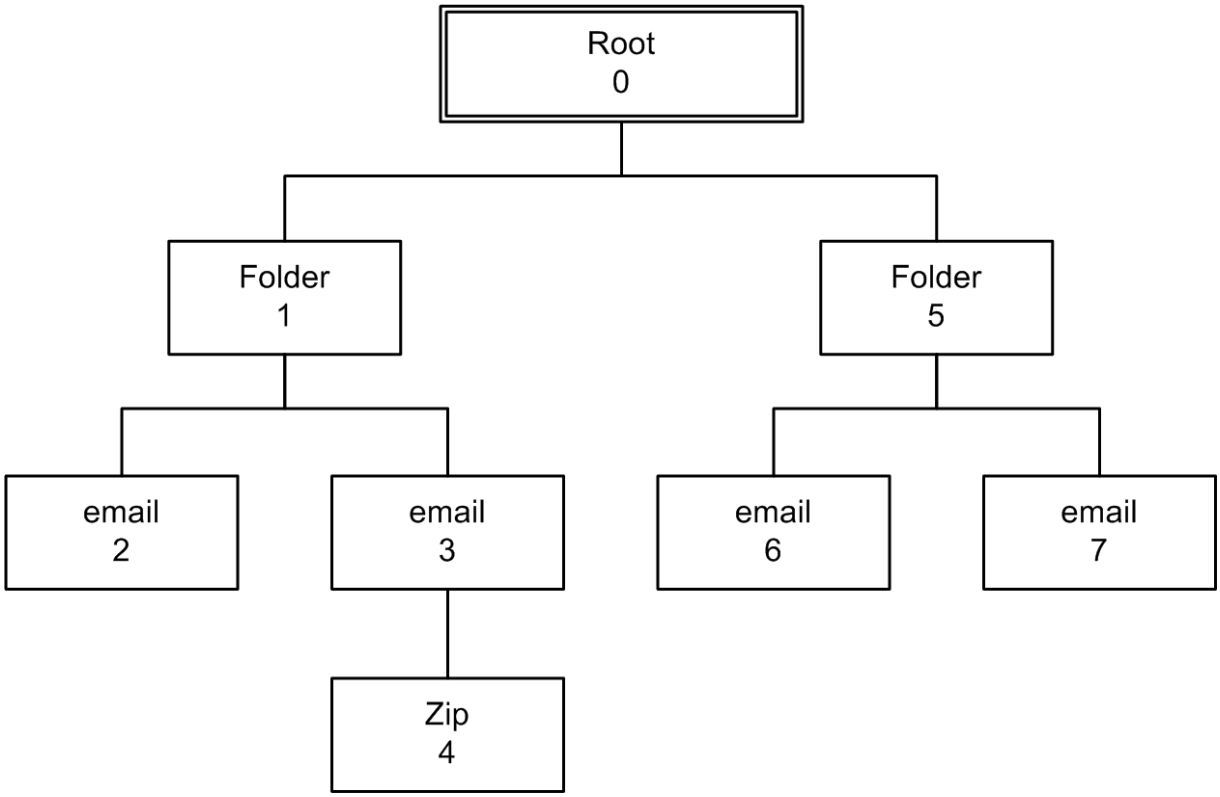
For example, you might extract a PST file that contains seven subfiles with a root node enabled. The call to `ExtractGetMainFileInfo()` returns the number of subfiles as 8 (seven subfiles and one root node). The following diagram shows the structure and the available hierarchy information after the subfiles are extracted:

Extracted PST file



The `ParentIndex` specifies the index number of a subfile's parent. The `ChildArray` specifies an array of a subfile's children. With this information, you can recreate the hierarchy shown in the following diagram.

Recreated file hierarchy



Extract Mail Metadata

You can extract metadata such as subject, sender, and recipient from MSG, EML, MBX, PST, and NSF files by calling the `ExtractGetSubFileMetadata` method. You can extract a predefined set of metadata fields and/or individual fields that are unique to a file format.

Default Metadata Set

KeyView internally defines a set of common mail metadata fields that can be extracted as a group from mail formats. This default metadata set is listed in the following table. When you retrieve all metadata for a file—that is, pass NULL for the array of metadata—the complete set of default metadata, not all available metadata in the file, is returned.

Default mail metadata list

Field Name (string to specify)	Description
`From`	The display name and email address of the sender.
`To`	The display names and email addresses of the recipients.

Default mail metadata list, continued

Field Name (string to specify)	Description
`Sent`	The time the message was sent.
`Cc`	The display names and email addresses of recipients who receive copies of the email.
`Bcc`	The display names and email addresses of recipients who received blind copies of the email.
`Subject`	The text in the subject line of the message.
`Priority`	The priority applied to the message.

Because mail formats use different terms for the same fields, the format's reader maps the default field name to the appropriate format-specific name. For example, when retrieving the default metadata set, the NSF field *Importance* is mapped to the name *Priority* and is returned.

You can also extract the default field names individually by passing the field name (such as *From*, *To*, and *Subject*); however, in this case, the string is not mapped to the format-specific name. For example, if you pass *Priority* in the call, you will retrieve the contents of the *Priority* field from an MBX file, but will not retrieve the contents of the *Importance* field from an NSF file.

> **NOTE:**
> You cannot pass the field names listed in the table individually for PST files. However, you can pass either the MAPI tag number or one of the constants in the Filter class as integers. See Microsoft Personal Folders File (PST) Metadata, on page 41.

Extract the Default Metadata Set

To extract the default metadata set, call the `ExtractGetSubFileMetadata(int extractFileId, int metadataID, string metaDataName)` method. For example:

```
int[] metaIDs = null;
string[] metaDataName = null;

m_objFilter.SetMetaConfig();

ExtractSubFileMetadata metadata;

metadata = m_objFilter.ExtractGetSubFileMetadata(extContextId, metaIDs,
metaDataName);
```

Microsoft Outlook (MSG) Metadata

In addition to the default metadata set, the metadata fields listed in the following table can be extracted for MSG files. The field name must be passed to `metaNameArray` in the call to the `ExtractGetSubFileMetadata` method.

MSG-specific metadata list

Field Name (string to specify)	Description
`AttachFileName`	An attachment's long file name and extension, excluding path.
`ConversationTopic`	The topic of the first message in a conversation thread. A conversation thread is a series of messages and replies. This is the first message's subject with any prefix removed.
`CreationTime`	The time the message or attachment was created. This value is displayed in the **Sent** field in the message's **Properties** dialog in Outlook.
`InternetMessageID`	The identifier for messages that come in over the Internet. This is the MAPI property `PR_INTERNET_MESSAGE_ID`. This property is not in the MAPI headers or MAPI documentation.
`LastModificationTime`	The time the message or attachment was last modified. This value is displayed in the **Modified** field in the message's **Properties** dialog in Outlook.
`MessageID`	The message transfer system (MTS) identifier for the message transfer agent (MTA). This value is displayed on the **Message ID** tab in the message's **Properties** dialog in Outlook.
`Received`	The date and time a message was delivered. This value is displayed in the **Received** field in the message's **Properties** dialog in Outlook.
`Sender`	The name and email address of the message sender. This value is a concatenation of two MAPI properties in the following format: `"PR_SENDER_NAME" <PR_SENDER_EMAIL_ADDRESS>` The `Sender` value might be the same as or different than the default metadata `From` value (see Default Metadata Set, on page 37), depending on which MAPI

MSG-specific metadata list, continued

Field Name (string to specify)	Description
	properties exist in the MSG file.
`Sensitivity`	The value indicating the message sender's opinion of the sensitivity of a message, such as Personal, Private, or Confidential. This value is displayed in the **Sensitivity** field in the message's **Properties** dialog in Outlook.
`TransportMsgHeaders`	Contains transport-specific message envelope information. This value corresponds to the MAPI property `PR_TRANSPORT_MESSAGE_HEADERS`.
`StartDate`	Contains an appointment start date. This value corresponds to the `PR_START_DATE` MAPI property.
`EndDate`	Contains an appointment end date. This value corresponds to the `PR_END_DATE` MAPI property.

Extract MSG-Specific Metadata

To extract specific metadata fields from an MSG file, use the method `ExtractGetSubFileMetadata (int extractFileId, int metadataID, string metaDataName)` and pass the field name defined in the table to `metaNameArray` (the string is not case sensitive).

For example, the following code extracts the contents of the `ConversationTopic` and `MessageID` fields:

```
int[] metaIDs = null;
string[] metaDataName = new string[2] {"conversationtopic", "MessageID"};

m_objFilter.SetMetaConfig();

ExtractSubFileMetadata metadata;
metadata = m_objFilter.ExtractGetSubFileMetadata(extContextId, metaIDs,
metaDataName);
```

Microsoft Outlook Express (EML) and Mailbox (MBX) Metadata

In addition to the default metadata set, you can extract any metadata field that exists in the header of an EML or MBX file by passing the field's name. If the name is a valid field in the file, the contents of the field are returned. For example, to retrieve the name of the last mail server that received the message before it was delivered, you can pass the string "`Received`".

Extract EML- or MBX-Specific Metadata

To extract specific metadata fields from an EML or MBX file, use the method `ExtractGetSubFileMetadata(int extractFileId, int metadataID, string metaDataName)` and pass the metadata name to `metaNameArray` (the string is not case sensitive).

For example, the following code extracts the contents of the `Received` and `Mime-version` fields:

```
int[] metaIDs = null;
string[] metaDataName = new string[2] {"Received", "Mime-version"};

m_objFilter.SetMetaConfig();

ExtractSubFileMetadata metadata;
metadata = m_objFilter.ExtractGetSubFileMetadata(extContextId, metaIDs,
metaDataName);
```

Lotus Notes Database (NSF) Metadata

In addition to the default metadata set, you can extract any Lotus field name that exists in an NSF file by passing the field's name. (You can extract fields from mail NSF files and non-mail NSF files.) If the name is a valid field in the file, the field is returned. For example, to retrieve the date a document in an NSF file was last accessed, you would pass the string "`$LastAccessedDB`".

> **NOTE:**
> A complete list of NSF fields are provided in the Lotus Notes file `stdnames.h`. This header file is available in the Lotus API Toolkit.

Extract NSF-Specific Metadata

To extract specific metadata fields from an NSF file, use the method `ExtractGetSubFileMetadata (int extractFileId, int metadataID, string metaDataName)` and pass the metadata name to `metaNameArray` (the string is not case sensitive).

For example, the following code extracts the contents of the `Description` and `Categories` fields:

```
int[] metaIDs = null;
string[] metaDataName = new string[2] {"description", "Categories"};

m_objFilter.SetMetaConfig();

ExtractSubFileMetadata metadata;
metadata = m_objFilter.ExtractGetSubFileMetadata(extContextId, metaIDs,
metaDataName);
```

Microsoft Personal Folders File (PST) Metadata

In addition to the default metadata set, you can extract Messaging Application Programming Interface (MAPI) properties from a PST file. These properties describe elements (subject, sender, recipient, and

so on) of Outlook items within the PST file. Since the properties are stored in the PST file itself, they can be retrieved before the contents of the PST are extracted. This enables you to determine whether an Outlook item should be extracted based on a subfile's attributes. MAPI properties are also stored for Outlook attachments that are not mail messages (such as an attached Microsoft Word document or Lotus 1-2-3 file).

MAPI Properties

Each MAPI property is identified by a property tag, which is a constant that contains the property type and a unique identifier. For example, the property that indicates whether a message has attachments has the following components:

Property	`PR_HASATTACH`
Identifier	`0x0E1B`
Property type	`PT_BOOLEAN (000B)`
Property tag	`0x0E1B000B`

The Microsoft MAPI documentation on the Microsoft Developer Network website lists all available MAPI properties, their tags, and types.

You can retrieve any MAPI property that is of one of the MAPI property types listed below:

`PT_I2`	`PT_DOUBLE`	`PT_STRING8`
`PT_I4`	`PT_FLOAT`	`PT_TSTRING`
`PT_BINARY`	`PT_LONG`	`PT_SYSTIME`
`PT_BOOLEAN`	`PT_SHORT`	`PT_UNICODE`

> **NOTE:**
> Properties with a `PT_TSTRING` type have the property type recompiled to either a Unicode string (`PT_UNICODE`) or to an ANSI string (`PT_STRING8`) depending on the operating system's character set. To retrieve the Unicode property, pass in the Unicode version of the tag. For example, the property tag for `PR_SUBJECT` is either `0x0037001E` for an ANSI string, or `0x0037001F` for a Unicode string.

Extract PST-Specific Metadata

In the call to extract subfile metadata, you can pass either the MAPI tag number (such as `0x0070001e`) or one of the constants in the Filter class (such as `KVPR_SUBJECT`). These constants are a subset of MAPI properties and use a KeyView naming convention. For example, the property `PR_CONVERSATION_TOPIC` is defined as `KVPR_CONVERSATION_TOPIC`. If the property you want to retrieve is not defined as a constant in the Filter class, you must pass the MAPI tag number.

To extract specific MAPI properties from a PST file, use the method `ExtractGetSubFileMetadata (int extractFileId, int metadataID, string metaDataName)` and pass the tag number or constant to `metaNameArray`.

For example, the following code extracts the MAPI properties `PR_SUBJECT` and `PR_ALTERNATE_RECIPIENT`:

```
int[] metaIDs = new int[2] { Filter.Constant.MAPIConstant.KVPR_SUBJECT, 0x3A010102
} ;
string[] metaDataName = null ;

m_objFilter.SetMetaConfig();

ExtractSubFileMetadata metadata;
metadata = m_objFilter.ExtractGetSubFileMetadata(extContextId, metaIDs,
metaDataName);
```

Exclude Metadata from the Extracted Text File

When a mail message is extracted, the message text and header information (`To`, `From`, `Sent`, and so on) is extracted to a text file. You can prevent the header information from appearing in the text file.

To exclude the header information, call the `ExcludeMailHeader` property of the `ExtractSubFileExtractConfig` object, and pass `ExtractSubFileExtractConfig` to the `ExtractSubFile` method. For example:

```
m_excludeMailHeader = true;
extconfig = new ExtractSubFileExtractConfig();

extconfig.ExcludeMailHeader = m_excludeMailHeader;
extinfo = m_objFilter.ExtractSubFile(extContextID, i, extconfig);
```

Extract Subfiles from Outlook Files

When an Outlook file (MSG) is extracted to disk, its message text and header information (`To`, `From`, `Sent`, and so on) are extracted to a text file. (If you do not want the header information to appear in the text file, see Exclude Metadata from the Extracted Text File, above.) If the Outlook file contains a non-mail attachment, the attachment is extracted in its native format to a sub directory. If the Outlook file contains a mail attachment, the attachment's message text and attachment(s) are extracted to a sub directory.

Extract Subfiles from Outlook Express Files

When an Outlook Express (EML) file is extracted to disk, its message text and header information (`To`, `From`, `Sent`, and so on) are extracted to a text file. (If you do not want the header information to appear in the text file, see Exclude Metadata from the Extracted Text File, above.) If the Outlook Express file contains a non-mail attachment, the attachment is extracted in its native format to the same directory as the message text file. If the Outlook Express file contains a mail attachment, the complete attachment (including message text and attachments), the message text file, and non-mail attachment (s) are extracted to the same directory as the main message.

> **NOTE:**
> When the MBX reader (`mbxsr`) is enabled, it is used to filter MBX and EML files. If the MBX reader is not enabled, the EML reader (`emlsr`) is used.

Extract Subfiles from Mailbox Files

A Mailbox (MBX) file is a collection of individual emails compiled with RFC 822 and RFC 2045 - 2049 (MIME), and divided by message separators. There are many mail applications that export to an MBX format, such as Eudora Email and Mozilla Thunderbird.

When an MBX file is extracted to disk, the message text and header information (`To`, `From`, `Sent`, and so on) from each mail file are extracted to text files. (If you do not want the header information to appear in the text file, see Exclude Metadata from the Extracted Text File, on the previous page.)

In Eudora MBX files, attachments are inserted as a link and are stored externally from the message. These attachments are not extracted, but the path to the attachment is returned in the call to the `ExtractGetSubFileInfo` method. You can write code to retrieve the attachment based on the returned path.

For MBX files from other clients, KeyView extracts attachments when they are embedded in the message.

> **NOTE:**
> The Mailbox (MBX) reader is an advanced feature and is sold and licensed separately. To enable this reader in a KeyView SDK, you must obtain the appropriate license key from HPE.

Extract Subfiles from Outlook Personal Folders Files

KeyView can extract Outlook items such as messages, appointments, contacts, tasks, notes, and journal entries from a PST file. When a PST file is extracted to disk, the body text and header information (`To`, `From`, `Sent`, and so on) from each Outlook item are extracted to a text file. (If you do not want the header information to appear in the text file, see Exclude Metadata from the Extracted Text File, on the previous page.)

You can also extract messages from PST files as MSG files, including all their attachments, using the `SaveAsMSG` property in the `ExtractSubFileExtractConfig` class.

If an Outlook item contains a non-mail attachment, the attachment is extracted in its native format to a sub directory. If an Outlook item contains an Outlook attachment, the attached item's body text and attachment(s) are extracted to a sub directory.

> **NOTE:**
> The Microsoft Outlook Personal Folders (PST) reader is an advanced feature and is sold and licensed separately. To enable this reader in a KeyView SDK, you must obtain the appropriate license key from HPE.

Use the Native or MAPI-based Reader

KeyView accesses PST files in one of two ways:

- indirectly using the Microsoft's Messaging Application Programming Interface (MAPI) reader named `pstsr`.
- directly using the native PST reader named `pstnsr`.

On UNIX and Windows x64 and IA-64, the native reader is always used to process PST files because the MAPI-based reader only runs on Windows x86. On Windows x86, you can specify either reader, however, the MAPI-based reader is used by default. The differences between the two readers are summarized in the following table:

Feature/Requirement	Native Reader (pstnsr)	MAPI-based Reader (pstsr)
All platforms supported	Yes	Windows x86 only
Outlook client required	No	Yes
MAPI properties supported	Yes All properties defined in `mapitags.h`. Object properties are not supported.	Yes Extracts properties defined in `mapitags.h`. Object properties are not supported.
Password-protection supported	Yes	Yes (using the `setPassword` method)
Compressible encryption supported	Yes	Yes
High encryption supported	No	Yes

To specify the MAPI-based reader be used for PST files, change the PST entry in the `formats.ini` file as follows:

```
297=pst
```

To specify the native reader be used for PST files, change the PST entry in the `formats.ini` file as follows:

```
297=pstn
```

> **NOTE:**
> You must make sure that the PST that you are extracting is not open in the Outlook client and the Outlook process is not running.

Use the Native PST Reader (pstnsr)

The native PST reader accesses PST files directly without relying on the Microsoft interface to the PST format. It runs on both Windows and UNIX and does not require an Outlook client on the system processing the PST files. However, the native reader does not support password-protected PST files that use high encryption.

Use the MAPI Reader (pstsr)

The `pstsr` reader accesses PST files indirectly using Microsoft's Messaging Application Programming Interface (MAPI). MAPI is a standard Windows message interface that enables different mail programs and other mail-aware applications (such as word processors and spreadsheets) to exchange messages and attachments with each other. MAPI allows KeyView to open a PST file, traverse the folders and Outlook items, and extract the items inside the PST file.

> **NOTE:**
> When extracting subfiles from PST files, information on the distribution list used in an email is extracted to a file called `emailname.dist`. This applies to the MAPI reader (pstsr) only.

System Requirements

Because MAPI is only supported on Windows platforms, you can only filter PST files on Windows. Because MAPI relies on functionality in Microsoft Outlook, a Microsoft Outlook client must be installed on the same machine as the application filtering PST files, and must be the default email application. KeyView supports the following PST formats and Outlook clients:

- Outlook 97 or higher PST files
- Outlook 2002 or Outlook 2003 clients

> **NOTE:**
> The Outlook client must be the same version as or newer than the version of Outlook that generated the PST file.

MAPI Attachment Methods

The way in which you can access the contents of a PST message attachment is determined by the MAPI attachment method applied to the attachment. For example, if the attachment is an embedded OLE object, it uses the `ATTACH_OLE` attachment method. KeyView can access message attachments that use the following attachment methods:

```
ATTACH_BY_VALUE
ATTACH_EMBEDDED_MSG
ATTACH_OLE
ATTACH_BY_REFERENCE
ATTACH_BY_REF_ONLY
ATTACH_BY_REF_RESOLVE
```

Attachments using the ATTACH_BY_VALUE, ATTACH_EMBEDDED_MSG, or ATTACH_OLE attachment methods are extracted automatically when the PST file is extracted. An "attach by reference" method means the attachment is not in Outlook, but Outlook contains an absolute path to the attachment. Before you can extract these types of attachments, you must retrieve the path to access the attachment.

To extract "attach by reference" attachments

1. Determine whether the attachment uses an ATTACH_BY_REFERENCE, ATTACH_BY_REF_ONLY, or ATTACH_BY_REF_RESOLVE method by retrieving the MAPI property PR_ATTACH_METHOD.
2. If the attachment uses one of the "attach by reference" methods, get the fully qualified path to the attachment by retrieving the MAPI properties PR_ATTACH_LONG_PATHNAME or PR_ATTACH_PATHNAME.
3. You can then either copy the files from their original location to the path where the PST file is extracted, or use the Filter API methods to filter the attachment.

Open Secured PST Files

KeyView enables you to specify credentials (user name and password), which are used to open a secured PST file for extraction. See Password Protected Files, on page 216 for more information.

Detect PST Files While the Outlook Client is Running

If you are running an Outlook client while running the File Extraction API, the KeyView format detection module (kwad) might not be able to open the PST file to determine the file's format because Outlook has the file locked. In this case, you can do one of the following:

- Close Outlook when using the Extraction API
- Detect PST files by extension only and bypass the format detection module. To enable this option, add the following lines to the formats.ini file.

```
[container_flags]
detectPSTbyExtension=1
```

> **NOTE:**
> The detectPSTbyExtension option only applies when you are using the MAPI reader (pstsr).

> **NOTE:**
> If you use this option, you must make sure in your code that valid PST files are passed to KeyView because the format detection module will not be available to verify the file type and pass the file to the appropriate reader.

Extract Subfiles from Lotus Domino XML Language Files

When a Lotus Domino XML Language (.DXL) file is extracted, its message text and header information (*To*, *From*, *Sent*, and so on) are extracted to a text file.

> **NOTE:**
> To prevent header information from being extracted, see Exclude Metadata from the Extracted Text File, on page 43.

You can make sure that dates and times extracted from Lotus Domino .DXL files are displayed in a uniform format.

To extract custom date/time formats

- In the formats.ini file, set the `DateTimeFormat` option in the `[dxlsr]` section. For example:

  ```
  [dxlsr]
  DateTimeFormat=%m/%d/%Y %I:%M:%S %p
  ```

  In this example, dates and times are extracted in the following format:

  02/11/2003 11:36:09 AM

  The format arguments are the same as those for the `strftime()` function. Refer to the following webpage for more information.

  http://msdn.microsoft.com/en-us/library/fe06s4ak%28VS.71%29.aspx

Extract Subfiles from Lotus Notes Database Files

A Lotus Notes database is a single file that contains multiple documents called *notes*. Notes include design notes (such as forms, views, folders, navigators, outlines, pages, framesets, agents, and resources), data document notes, profile document notes, access control list notes, and collection (index) notes. KeyView can extract text items, attachments, and OLE objects from *data document notes* only. Data document notes include emails, journal entries, discussion threads, documents (Microsoft Office and Lotus SmartSuite), and so on.

All components of a note are prefixed by field names such as "`SendTo:`", "`Subject:`", and "`Body:`". When a note is extracted, the field names are not included in the extracted output; only the field values are extracted.

When a mail message in an NSF file is extracted to disk, the body text and header information— such as the values from the `SendTo`, `From`, and `DeliveredDate` fields—in each message are extracted to a text file. (If you do not want the header information to appear in the message text file, see Exclude Metadata from the Extracted Text File, on page 43.)

> **NOTE:**
> The Lotus Notes Database (NSF) reader is an advanced feature and is sold and licensed separately. To enable this reader in a KeyView SDK, you must obtain the appropriate license key from HPE.

System Requirements

The NSF format is proprietary. Therefore, KeyView accesses NSF files indirectly using the Lotus Notes API. Since the NSF reader relies on functionality in Lotus Notes, a Lotus Notes client or Lotus Domino server must be installed and configured on the same machine on which the application filtering

NSF files is installed. On UNIX and Linux, the Lotus Domino server is required. On Windows, the Lotus Notes client or Lotus Domino server is required.

KeyView supports the following Lotus Notes clients and Domino servers:

- Lotus Notes 6.5.1
- Lotus Domino 6.5.1

KeyView supports NSF files on the same platforms supported by Lotus Notes and Lotus Domino:

- Windows XP x86 (Service Pack 1 and 2)
- Windows 2000 x86 (Service Pack 2)
- Solaris 8.0 and 9.0 (built on Solaris 8.0)
- Red Hat Enterprise Linux AS 3.0 (x86)
- SuSE Linux Enterprise Server 8 and 9 (x86)
- IBM AIX 5.1, 5L version 5.2

Installation and Configuration

Before KeyView can filter NSF files, you must set up the Lotus Notes client or Lotus Domino server. Full configuration is not required. The following steps outline the minimal setup for NSF filtering.

Windows

1. Install the Lotus Notes client or Lotus Domino server. You do not need to configure the client or server.
2. Make sure that the `notes.ini` file is in the *`install`*`\lotus\notes` directory, where *`install`* is the directory where Lotus Notes is installed. If the file does not exist, create an ASCII file named `notes.ini`, and add the following text:

   ```
   [Notes]
   ```

3. Add the *`install`*`\lotus\notes` and the KeyView `bin` directory to the `PATH` environment variable. HPE recommends that you add the KeyView `bin` directory because the Lotus Notes installation might contain older KeyView OEM libraries.

Solaris

1. Install Lotus Domino server. You do not need to configure the server.
2. Make sure that the `notes.ini` file is in the *`install`*`/lotus/notes/latest/sunspa` directory, where *`install`* is the directory where Lotus Notes is installed. If the file does not exist, create an ASCII file named `notes.ini`, and add the following text:

   ```
   [Notes]
   ```

3. Add the *`install`*`/lotus/notes/latest/sunspa` directory to the `PATH` environment variable:

   ```
   setenv PATH install/lotus/notes/latest/sunspa:$PATH
   ```

4. Add the *`install`*`/lotus/notes/latest/sunspa` and the KeyView `bin` directory to the `LD_LIBRARY_PATH` environment variable:

```
setenv LD_LIBRARY_PATH keyview_bin:install/lotus/notes/latest/sunspa:$LD_
LIBARY_PATH
```

where *keyview_bin* is the location of the KeyView `bin` directory. HPE recommends that you add the KeyView `bin` directory because the Lotus Notes installation might contain older KeyView OEM libraries.

AIX 5.x

1. Install the `bos.iocp.rte` file set if it is not already installed, and reboot the machine. See the Lotus Domino server documentation for more information.
2. Install Lotus Domino server. You do not need to configure the server.
3. Make sure that the `notes.ini` file is in the *install*`/lotus/notes/latest/ibmpow` directory, where *install* is the directory where Lotus Notes is installed. If the file does not exist, create an ASCII file named `notes.ini`, and add the following text:

   ```
   [Notes]
   ```

4. Add the *install*`/lotus/notes/latest/ibmpow` directory to the `PATH` environment variable:

   ```
   setenv PATH install/lotus/notes/latest/ibmpow:$PATH
   ```

5. Add the *install*`/lotus/notes/latest/ibmpow` and the KeyView `bin` directory to the `LIBPATH` environment variable:

   ```
   setenv LIBPATH keyview_bin:install/lotus/notes/latest/ibmpow:$LIBPATH
   ```

   where *keyview_bin* is the location of the KeyView `bin` directory. HPE recommends that you add the KeyView `bin` directory because the Lotus Notes installation might contain older KeyView OEM libraries.

Linux

1. Install Lotus Domino server. You do not need to configure the server.
2. Make sure that the `notes.ini` file is in the *install*`/lotus/notes/latest/linux` directory, where *install* is the directory where Lotus Notes is installed. If the file does not exist, create an ASCII file named `notes.ini`, and add the following text:

   ```
   [Notes]
   ```

3. Add the *install*`/lotus/notes/latest/linux` directory to the `PATH` environment variable:

   ```
   setenv PATH install/lotus/notes/latest/linux:$PATH
   ```

4. Add the *install*`/lotus/notes/latest/linux` and the KeyView `bin` directory to the `LD_LIBRARY_PATH` environment variable:

   ```
   setenv LD_LIBRARY_PATH keyview_bin:install/lotus/notes/latest/linux:$LD_
   LIBRARY_PATH
   ```

   where *keyview_bin* is the location of the KeyView `bin` directory. HPE recommends that you add the KeyView `bin` directory because the Lotus Notes installation might contain older KeyView OEM libraries.

Open Secured NSF Files

KeyView enables you to specify credentials (user ID file and password), which are used to open a secured NSF file for extraction. See Password Protected Files, on page 216 for more information.

Format Note Subfiles

The KeyView NSF reader uses XML templates to format note sub-files. You can customize the templates as required to approximate the look and feel of the original notes as closely as possible. For more information, see Extract and Format Lotus Notes Subfiles, on page 153.

Extract Subfiles from PDF Files

KeyView can extract document-level and page-level attachments from a PDF document. Document-level attachments are added by using the **Attach A File** tool, and can include links to or from the parent document or to other file attachments. Page-level attachments are added as comments by using various tools. Page-level or comment attachments display the File Attachment icon or the Speaker icon on the page where they are located.

When a PDF file is extracted to disk, the PDF file is extracted to a directory and the PDF's attachments are saved in their native format to the same directory as the original PDF file.

Improve Performance for PDFs with Many Small Images

To improve performance when processing PDF files that contain many small images, you can choose to ignore images unless they exceed a minimum width and/or height. If an image is smaller than the minimum width or height, KeyView does not extract the image.

For example, to ignore images that are less than 16 pixels wide or less than 16 pixels in height, add the following to the `[pdf_flags]` section of the `formats.ini` file:

```
[pdf_flags]
process_images_with_min_width=16
process_images_with_min_height=16
```

Extract Embedded OLE Objects

The File Extraction API can extract embedded OLE objects from the following types of documents:

- Microsoft Excel
- Microsoft Word
- Microsoft PowerPoint
- Microsoft Outlook
- Microsoft Visio
- Rich Text Format (RTF)

When an embedded OLE object is extracted from its parent file, the location where the embedded file appears in the original document is not available. The parent and child are extracted as separate files.

Extract Subfiles from ZIP Files

ZIP files that are not password-protected can be extracted using the general method (see Extract Subfiles, on page 34). However, some ZIP files use password protection, in which case you must use a different method to enter the required credentials. See Password Protected Files, on page 216 for more information.

Default File Names for Extracted Subfiles

When a file name is not specified in the call to `ExtractSubFile`, in some cases, a default file name is applied to the extracted subfile.

Default File Name for Mail Formats

To avoid naming conflicts and problems with long file names, KeyView applies its own names to the extracted mail folders and mail items when a name is not supplied in the call to `ExtractSubFile`. A non-mail attachment retains its original file name and extension.

When the contents of a mail store or the message body of a mail message are extracted, the extracted file names might include the following:

- The first valid eight characters of the original folder name or “Subject” line of the mail message. If the “Subject” line is empty, the characters `kvext` are used, where `ext` is the format’s extension. For example, the characters would be “`kvmsg`” for MSG, and “`kvnsf`” for NSF.

  The following special characters are considered invalid and are ignored:

  - any non-printing character with a value less than `0x1F`
  - angle brackets (< >)
  - asterisk (*)
  - back slash (\)
  - colon (:)
  - double quote (“)
  - forward slash (/)
  - pipe (|)
  - question mark (?)

  For notes, the file name is derived from the first 24 characters of the note text. For contact entries, the file name is derived from the full name of the contact.
- The characters `_kvn`, where `n` is an integer incremented from 0 for each extracted item.
- One of the following extensions:

Type	File Extension
email message	`.mail` `.rtf` (NSF files)
calendar appointment	`.cal`
contact entry	`.cont`
task entry	`.task`
note	`.note`
journal entry	`.jrnl`
distribution list	`.dist`

If the type cannot be determined for an MSG or PST file, the file is given a `.mail` extension.

If the type cannot be determined for an NSF file, the file is given a `.tmp` extension.

For example, an MSG mail message with the subject line "`RE: Product roadmap`" that contains the Microsoft Excel attachment `release_schedule.xls` is extracted as:

```
RE produ_kv0.mail
release_schedule.xls
```

If an extracted message contains an embedded OLE object or any attachment that does not have a name, the object or attachment is extracted as `_kv#.tmp`.

Default File Name for Embedded OLE Objects

KeyView can apply a default name to an extracted embedded OLE object when a name is not supplied in the call to `ExtractSubFile`. When an embedded OLE object is extracted, the extracted file name might include the following:

- The first valid eight characters of the main file. The following special characters are considered invalid and are ignored:
  - any non-printing character with a value less than `0x1F`
  - angle brackets (< >)
  - asterisk (*)
  - back slash (\)
  - colon (:)
  - double quote (")
  - forward slash (/)
  - pipe (|)
  - question mark (?)
- The characters `_kvn`, where `n` is an integer incremented from 0 for each extracted object.
- If KeyView can determine the embedded OLE is a Microsoft Office document, the original extension is used. If the file type cannot be determined, the file is given a `.tmp` extension.

For example, let us say a Microsoft Word document (`sales_quarterly.doc`) contains two embedded OLE objects: a Microsoft Excel file called `west_region.xls`, and a bitmap created in the Word document. The embedded objects would be extracted as

```
sales_qu_kv0.xls
sales_qu_kv1.tmp
```

Chapter 4: Use the Filter API

This section describes how to perform some basic filtering tasks by using the Filter API.

Generate an Error Log

You can monitor and debug filtering operations by enabling a detailed error log. This allows you to see errors that are generated at run time and to track problem files in stream or file mode.

> **NOTE:**
> Error logs are not generated when in-process filtering is enabled.

The error log might include the following information:

- Generated error messages.
- Time stamp.
- Path and file name of the file in which the error occurred.
- Length of the file in which the error occurred. If the name of the original file or the name of the temporary file are not obtained in stream mode, the file length is reported.

The following is a sample log file:

```
-KVOOPE 12 # Time: 11:14:32 # File Len = 68140
-KVOOPE 13 # Time: 11:23:05 # H:\files\WP\Word97\fnldmsa.doc
-KVOOPE  5 # Time: 12:15:54 # H:\files\SS\XL2000\corporate.xsl
-KVOOPE  5 # Time: 12:45:19 # H:\files\WP\WPerf5\wp501.doc
-KVOOPE 12 # Time: 14:25:33 # H:\files\PG\PPoint95\95.ppt
-KVOOPE 26 # Time: 16:26:04 # File Len = 19117568
-KVOOPE 10 # Time: 20:27:40 # File Len = 19117568
```

You can specify the information that is written to the log file using either the API or environment variables. To configure a log file for a single filtering session, use environment variables. To configure a

log file for all filtering sessions, use the API. Configuring the log file using the API overrides the same settings in the environment variables. You can also specify additional settings in the `formats.ini` file

You can configure the following features of the log file:

- Enable or disable logging. See Enable or Disable Error Logging, below.
- Change the default path and file name of the log file. See Change the Path and File Name of the Log File, below.
- Include memory errors in the log file. See Report Memory Errors, on the next page.
- Specify a memory guard that is used to generate memory overwrite errors in the log. See Specify a Memory Guard, on the next page.
- Include the input file name in the log file when filtering a stream. See Report the File Name in Stream Mode, on the next page.
- Specify the maximum size of the log file. See Specify the Maximum Size of the Log File, on page 58.

Enable or Disable Error Logging

You can enable or disable error logging using either the API or environment variables. By default, a file called `kvoop.log` is created in the system temporary directory; however, you can change the path and file name of this file (see Change the Path and File Name of the Log File, below).

Use the API

To enable or disable logging in the API, instantiate the Filter object using the constructor `Filter (String outputCharSet, UInt32 filterFlags)`, and set the `FilterConstant.FilterFlagConstant` argument to either `FILTERFLAG_OOPLOGON` or `FILTERFLAG_OOPLOGOFF`. For example:

```
objFilter = new Filter(outputCharSet, FilterConstant.FilterFlagConstant.FILTERFLAG_OOPLOGON);
```

Use Environment Variables

To enable logging, add the environment variable `KVOOPLOGON`, and set the variable value to 1. To disable logging, do not set the environment variable `KVOOPLOGON`.

Change the Path and File Name of the Log File

You can change the default path and file name of the log file. The default is `C:\temp\kvoop.log` on Windows and `/tmp/kvoop.log` on UNIX.

To change the path and file name of the log file, add the following to the `formats.ini` file:

```
[kvooplog]
KvoopLogName=filepath
```

The `formats.ini` file is in the directory `install\`*OS*`\bin`, where `install` is the path name of the Filter installation directory and `OS` is the name of the operating system.

Report Memory Errors

You can report memory leaks and memory overwrites in the log file by enabling the memory trace system, either by using the API or environment variables. If the memory trace system is enabled, the error messages for memory leaks and memory overwrites (`KVError_MemoryLeak` and `KVError_MemoryOverwrite`, respectively) are reported in the log file when they are generated.

> **NOTE:**
> To report memory overwrites, you must also set a memory guard. See Specify a Memory Guard, below.

Use the API

To enable or disable the memory trace system in the API, instantiate the Filter object using the constructor `Filter(String outputCharSet, UInt32 filterFlags)`, and set the `FilterConstant.FilterFlagConstant` argument to either **`FILTERFLAG_OOPMEMTRACEON`** or **`FILTERFLAG_OOPMEMTRACEOFF`**. For example:

```
objFilter = new Filter(outputCharSet, FilterConstant.FilterFlagConstant.FILTERFLAG_
OOPMEMTRACE);
```

Use Environment Variables

To enable the memory trace system, add the `KVOOPMT` environment variable, and set its value to **`1`**. To disable the memory trace system, do not set the `KVOOPMT` environment variable.

Specify a Memory Guard

To report memory overwrites in the log file, you must set a memory guard that protects against memory overwrites. Normally, this is set in the range of 100-200 bytes. For example, if a memory guard of 100 is set and 20 bytes of memory are specified, a total of 120 bytes of memory are allocated. The additional memory is used to monitor and identify memory overwrites.

To configure the memory guard, add the following section to the `formats.ini` file:

```
[Kvooplog]
mg=100
```

Report the File Name in Stream Mode

When you run Filter in file mode the file name is always reported in the log file. To report the file name in stream mode, you must extract it through the API.

To add the input file name to the log

1. Create an instance of `ConfigOption` with the following properties:
   a. Set the `ConfigOptionType` to `CFG_SETOOPSRCFILE`.
   b. Set the `ConfigOptionValue` to 0.
   c. Set `ConfigOptionData` to the `input_filename`.
2. Call the `SetConfigOption` method, and pass in the `ConfigOption` instance.

Example

```
ConfigOption configs = new ConfigOption();
    configs.ConfigOptionData = input_filename;
    configs.ConfigOptionType = FilterConstant.ConfigOptionConstant.CFG_
SETOOPSRCFILE;
    configs.ConfigOptionValue = 0;
    objFilter.SetConfigOption(configs);
```

Specify the Maximum Size of the Log File

You can specify the maximum size of the log file. When this size is reached and new entries are logged, either the first entry in the file is overwritten or the new entries are not reported.

To configure the maximum log size and whether old entries are overwritten, add the following section to the `formats.ini` file:

```
[Kvooplog]
LogFileSize=10
OverWriteLog=1
```

Option	Description
`LogFileSize`	This option specifies the maximum size of the log file in KB. The minimum is 1 K. If a size is not specified, the default 2 MB is used.
`OverWriteLog`	This option determines whether the log file is overwritten when the maximum log file size (`LogFileSize`) is reached. If you set this option to **`1`**, the first entry of the log file is overwritten. If you set this option to **`0`**, new entries are not reported in the log file.

Extract Metadata

When a file format supports metadata, KeyView can extract and process that information. Metadata includes document information fields such as title, author, creation date, and file size. Depending on the file's format, metadata is referred to in a number of ways: for example, "summary information," "OLE summary information," "file information," and "document properties."

The metadata in mail formats (MSG and EML) and mail stores (PST, NSF, and MBX) is extracted differently than other formats. For information on extracting metadata from these formats, see Extract Mail Metadata, on page 37.

> **NOTE:**
> KeyView can extract metadata from a document only if metadata is defined in the document, and if the document reader can extract metadata for the file format. The section Supported Formats, on page 84 lists the file formats for which metadata can be extracted. KeyView does not generate metadata automatically from the document contents.

The sample code `TestFilter` demonstrates how to extract metadata. See TestFilter, on page 79.

Extract Metadata for File Filtering

To extract metadata for file filtering

1. Optionally, set the input source using the `SetInputSource(String inFile)` method of the `Filter` object.
2. If the input source was set in step 1, call the `GetSummaryInfo()` method of the `Filter` object to retrieve an object of the `SummaryInfo` class. Otherwise, call the `GetSummaryInfo(String inFile)` method.
3. Use the methods of the `SummaryInfo` object to retrieve the metadata information.

Extract Metadata for Stream Filtering

To extract metadata for stream filtering

1. Optionally, set the input source using the `SetInputSource(System.IO.Stream input)` method of the `Filter` object.
2. If the input source was set in step 1, call the `GetSummaryInfo()` method of the `Filter` object to retrieve an object of the `SummaryInfo` class. Otherwise, call the `GetSummaryInfo (System.IO.Stream in)` method.
3. Use the methods of the `SummaryInfo` object to retrieve the metadata information.

Example

Below is an example of a call to `GetSummaryInfo()`:

If the get summary flag `-i` is set:

```
List<SummaryInfoElement> sinfo sinfo = objFilter.GetSummaryInfo();
if(sinfo != null)
{
   FileStream fs = new FileStream(m_summaryFile, FileMode.OpenOrCreate,
FileAccess.Write);
   StreamWriter sw = new StreamWriter(fs);
   //In case the ANSI is not 1252, using following to get byte array and then
convert to correct information.
```

```
   // BinaryWriter bw = new BinaryWriter(fs);
   string charSet = objFilter.TargetCharSet;
   foreach (SummaryInfoElement item in sinfo)
{
  Console.WriteLine( item.ElementName + ". data: " + item.Data );
  if (item.ElementName != null)
  {
    //bw.Write(item.ElementNameByteArray);
    sw.WriteLine(" name: " + item.ElementName );
  }
  if (item.Data != null)
  {
    //bw.Write(item.DataByteArray);
    sw.WriteLine(" data: " + item.Data );
  }
  sw.Flush();
  }
  sw.Close();
  fs.Close();
}
sinfo=null;
```

The `SummaryInfo` class stores the metadata extraction results. After calling the `Filter.GetSummaryInfo()`method, call the properties provided by each instance of this class to extract metadata. The following describes each property:

- `Isvalid`. Specifies whether the element data is present.
- `SumInfoType`. Sets or gets the summary element's data type. The possible types are:

`KV_String`	The value in the metadata field is a string.
`KV_Int4`	The value in the metadata field is an integer.
`KV_DateTime`	The value in the metadata field is a date and time.
`KV_ClipBoard`	Currently not supported.
`KV_Bool`	The value in the metadata field is a boolean.
`KV_Unicode`	The value in the metadata field is a Unicode string.
`KV_IEEE8`	The value in the metadata field is an IEEE 8-byte integer.
`KV_Other`	The value in the metadata field is user-defined.

- `Data`. Sets or gets the summary element's content.

  If `type` is `KV_Int4` or `KV_Bool`, then `data` contains the actual value. Otherwise, `Data` is a pointer to the actual value.

  `KV_IEEE8` point to an 8-byte value.

  `KV_DateTime` , `KV_String` and `KV_Unicode` point to the beginning of the string that contains the text. `KV_Unicode` is replaced with `KV_String` when the UNICODE value has been character mapped to the desired output character set.

- `ElementName`. Sets or gets the summary element's name.
- `ElementNameByteArray`. Sets or gets the summary element's name using a byte array in case the character set is not known.
- `DataByteArray`. Gets the summary element's content using a byte array.

  If the `SumInfoType` is `KV_DateTime` , the value in the `DataByteArray` is a 64-bit value representing the number of 100-nanosecond intervals since January 1, 1601 (Windows FILETIME EPOCH). You might need to convert this value into another format.

Convert Character Sets

Filter can convert the character set of a source document to an arbitrary character set specified in the API, or to the character set of the operating system on which the output text is viewed. For this conversion to occur, a source character set *must* be identified. The source character set can either be determined by the document reader, or can be set in the API. The section Supported Formats, on page 84 lists file formats for which character set information can be determined by the document reader. The character sets are defined as constants in the Filter class.

Determine the Character Set of the Output Text

To determine the output character set of a filtered document, Filter considers the following:

- Whether the document reader can determine the character set of the file format. If the document reader cannot determine the character set information for the document type, set the source character set in the API.
- Whether the *source* character set is specified in the API.
- Whether the *target* character set is specified in the API.

Guidelines for Character Set Conversion

Below are some rules for the determination of character set mapping:

- If the source is not determined by the document reader or configured in the API, then the character set of the output text is always unknown, regardless of the target character set configuration. The document cannot be converted to a target character set or the operating system's code page unless the source character set is known.
- If the target character set is *not* specified in the API, and the source character set is identified, then the operating system's code page is used for the output text.
- If the source character set is identified, and the target character set is specified in the API, then the target character set specified in the API is used for the output text.
- For documents that contain multiple character sets, HPE recommends that the target character set be forced to UNICODE or UTF-8.

Determining the Output Character Set—Example, on the next page illustrates how Filter determines the character set of the output text.

Determining the Output Character Set—Example

Source charset read by Filter	Source charset specified in API	Target charset specified in API	Output charset
No	No	No	no conversion
No	KVCS_936	No	OS code page
No	No	UNICODE	no conversion
No	KVCS_936	UNICODE	UNICODE
Yes	No	No	OS code page
Yes	KVCS_936	No	OS code page
Yes	No	UNICODE	UNICODE
Yes	KVCS_936	UNICODE	UNICODE

Set the Character Set During Filtering

You can convert the character set of a file at the time the file is filtered.

To specify the source character set, use the `SourceCharSet` property. For example:

```
objFilter.SourceCharSet=sourceCharSet;
```

To specify the target character set, instantiate the Filter object using the constructor `Filter(String outputCharSet, UInt32 filterFlags)`. For example:

```
objFilter = new Filter(outputCharSet, filterFlags);
```

Set the Character Set During Subfile Extraction

You can convert the character set of a subfile at the time the subfile is extracted from the container. This is most often used to set the character set of a mail message's body text. See Filter PDF Files, on page 64 for more information.

To specify the source and target character set of a subfile

1. Use the methods of the `ExtractSubFileExtractConfig` object to set the source and target character set.
2. Call the `ExtractSubFile` method of the Filter object and pass in the `ExtractSubFileExtractConfig` object. For example:

```
subFileConfig.FilePath = subInfo.SubFileName;
subFileConfig.ExtractDirectory = m_extractDir;
subFileConfig.CreateDirectory = m_createDir;
subFileConfig.OverWrite = true;
subFileConfig.ExcludeMailHeader = m_excludeMailHeader;
subFileConfig.GetFormattedBody = m_getFormattedBody;
subFileConfig.SourceCharset = m_sourceCharSet;
subFileConfig.TargetCharset = m_outputCharSet;
subFileConfig.LittleEndian = m_isLittleEnd == 1 ? true : false;
```

Prevent the Default Conversion of a Character Set

You can prevent the default conversion of text to the operating system code page, and specify that Filter retain the original character encoding of the document when it is available. Any document identified as containing more than one character encoding is converted to the first encoding encountered in the file.

To prevent the default conversion, instantiate the Filter object using the constructor `Filter(String outputCharSet, UInt32 filterFlags)`, and set the `FilterConstant.FilterFlagConstant` argument to `FILTERFLAG_NODEFAULTCHARSETCONVERT`. For example:

```
objFilter = new Filter(outputCharSet, FilterConstant.FilterFlagConstant.FILTERFLAG_
NODEFAULTCHARSETCONVERT);
```

This setting overrides the source or target character set specified in the API.

Extract Deleted Text Marked by Tracked Changes

The revision tracking feature in applications—such as Microsoft Word's **Track Changes**—marks changes to a document (typically, strikethrough for deleted text and underline for inserted text) and tracks each change by reviewer name and date. If revision tracking was enabled when text was deleted from a source document, you can configure Filter to extract the deleted text. Filter does not extract the reviewer name and revision date. Deleted text is excluded from the filtered output by default.

To extract deleted text from a document and include it in the filtered output, use the `IncludeRevsionMark` property. For example:

```
if(inclRevisionMark == true)
{
    objFilter.IncludeRevisionMark();
}
```

To reset the flag and exclude deleted text from the filtered output, call the `ExcludeRevsionMark` method. For example:

```
if(inclRevisionMark == false)
{
    objFilter.ExcludeRevisionMark();
}
```

Filter PDF Files

Filter has special configuration options that allow greater control over the conversion of Adobe Acrobat PDF files.

Filter PDF Files to a Logical Reading Order

The PDF format is primarily designed for presentation and printing of brochures, magazines, forms, reports, and other materials with complex visual designs. Most PDF files do not contain the *logical structure* of the original document—the correct reading order, for example, and the presence and meaning of significant elements such as headers, footers, columns, tables, and so on.

KeyView can filter a PDF file either by using the file's internal unstructured paragraph flow, or by applying a structure to the paragraphs to reproduce the logical reading order of the visual page. Logical reading order enables KeyView to output PDF files that contain languages that read from right-to-left (such as Hebrew and Arabic) in the correct reading direction.

> **NOTE:**
> The algorithm used to reproduce the reading order of a PDF page is based on common page layouts. The paragraph flow generated for PDFs with unique or complex page designs might not emulate the original reading order exactly.
>
> For example, page design elements such as drop caps, callouts that cross column boundaries, and significant changes in font size might disrupt the logical flow of the output text.

By default, KeyView produces an *unstructured* text stream for PDF files. This means that PDF paragraphs are extracted in the order in which they are stored in the file, not the order in which they appear on the visual page. For example, a three-column article could be output with the headers and title at the end of the output file, and the second column extracted before the first column. Although this output does not represent a logical reading order, it accurately reflects the internal structure of the PDF.

You can configure KeyView to produce a *structured* text stream that flows in a specified direction. This means that PDF paragraphs are extracted in the order (logical reading order) and direction (left-to-right or right-to-left) in which they appear on the page.

The following paragraph direction options are available:

Paragraph Direction Option	Description
Left-to-right	Paragraphs flow logically and read from left to right. You should specify this option when most of your documents are in a language that uses a left-to-right reading order, such as English or German.
Right-to-left	Paragraphs flow logically and read from right to left. You should specify this option when most of your documents are in a language that uses a right-to-left reading order, such as Hebrew or Arabic.
Dynamic	Paragraphs flow logically. The PDF filter determines the paragraph direction for each PDF page, and then sets the direction

Paragraph Direction Option	Description
	accordingly. Filter uses this option when a paragraph direction is not specified.

> **NOTE:**
> Filtering might be slower when logical reading order is enabled. For optimal speed, use an unstructured paragraph flow.

The paragraph direction options control the direction of paragraphs on a page; they do not control the text direction in a paragraph. For example, a PDF file might contain English paragraphs in three columns that read from left to right, but 80% of the second paragraph might contain Hebrew characters. If the left-to-right logical reading order is enabled, the paragraphs are ordered logically in the output—title paragraph, then paragraph 1, 2, 3, and so on—and flow from the top left of the first column to the bottom right of the third column. However, the *text* direction of the second paragraph is determined independently of the page by the PDF filter, and is output from right to left.

> **NOTE:**
> Extraction of metadata is not affected by the paragraph direction setting. The characters and words in metadata fields are extracted in the correct reading direction regardless of whether logical reading order is enabled.

Enable Logical Reading Order

You can enable logical reading order by using either the API or the `formats.ini` file. Setting the paragraph direction in the API overrides the setting in the `formats.ini` file.

Use the API

To enable PDF logical reading order in the API, use the `PDFLogicalOrder` property, and set the `orderFlag` argument to one of the following flags:

Flag	Description
`PDF_LOGICAL_ORDER_LTR`	Logical reading order and left-to-right paragraph direction
`PDF_LOGICAL_ORDER_RTL`	Logical reading order and right-to-left paragraph direction
`PDF_LOGICAL_ORDER_AUTO`	Logical reading order. The PDF reader determines the paragraph direction for each PDF page, and then sets the direction accordingly. Filter uses this option when a paragraph direction is not specified.
`PDF_LOGICAL_ORDER_RAW`	Unstructured paragraph flow. This is the default behavior. If logical reading order is enabled, and you want to return to an unstructured paragraph flow, set this flag.

For example:

```
objFilter.PDFLogicalOrder=FilterConstant.PDFFileConstant.PDF_LOGICAL_ORDER_LTR;
```

Use the formats.ini File

The `formats.ini` file is in the directory *`install`*`\`*`OS`*`\bin`, where *`install`* is the path name of the Filter installation directory and *`OS`* is the name of the operating system.

To enable logical reading order by using the `formats.ini` file

1. Change the PDF reader entry in the `[Formats]` section of the `formats.ini` file as follows:

   ```
   [Formats]
   200=lpdf
   ```

2. Optionally, add the following section to the end of the `formats.ini` file:

   ```
   [pdf_flags]
   pdf_direction=paragraph_direction
   ```

   where `paragraph_direction` is one of the following:

Flag	Description
`LPDF_LTR`	Left-to-right paragraph direction
`LPDF_RTL`	Right-to-left paragraph direction
`LPDF_AUTO`	The PDF filter determines the paragraph direction for each PDF page, and then sets the direction accordingly. Filter uses this option when a paragraph direction is not specified.
`LPDF_RAW`	Unstructured paragraph flow. This is the default behavior. If logical reading order is enabled, and you want to return to an unstructured paragraph flow, set this flag.

Rotated Text

When a PDF that contains rotated text is filtered, the rotated text is extracted after the text at the end of the PDF page on which the rotated text appears. If the PDF is filtered with logical order enabled, and the amount of rotated text on a page surpasses a predefined threshold, the page is automatically output as an unstructured text stream. You cannot configure this threshold.

Extract Custom Metadata from PDF Files

To extract custom metadata from your PDF files, add the custom metadata names to the `pdfsr.ini` file provided, and copy the modified file to the `bin` directory. You can then extract metadata as you normally would.

The `pdfsr.ini` is in the directory `samples\pdfini`, and has the following structure:

```
<META>
<TOTAL>total_item_number</TOTAL>,
```

```
/metadata_tag_name datatype,
</META>
```

Parameter	Description
`total item number`	The total number of metadata tags that are listed.
`metadata_tag_name`	The metadata tag name used in the PDF files.
`datatype`	The data type of the metadata element. The possible types are: • `KV_String` • `KV_Int4` • `KV_DateTime` • `KV_ClipBoard` • `KV_Bool` • `KV_Unicode` • `KV_IEEE8` • `KV_Other`

For example:

```
<META>
<TOTAL>4</TOTAL>
/part_number      INT4
/volume           INT4
/purchase_date    DATETIME
/customer         STRING
</META>
```

Skip Embedded Fonts

Text in PDF files sometimes contain embedded fonts. If you experience difficulties filtering embedded fonts, there are options in the API, the `formats.ini` file, and the FilterTestDotNet sample program that you can set to skip this type of text.

> **NOTE:**
> If you choose to skip embedded fonts, none of the content that contains embedded fonts is included in the output.

Use the formats.ini File

The `formats.ini` file is in the directory `install\`*`OS`*`\bin`, where `install` is the path name of the Filter installation directory and `OS` is the name of the operating system.

When you use `formats.ini` to skip embedded fonts, you can also specify an *embedded font threshold*, which is an arbitrary percentage probability that the glyph in the embedded text maps to a character value in the output character set (ASCII, UTF-8, and so on).

For example, if you specify a threshold of `75`, embedded text glyphs that have a 75% or greater probability of correctly matching the character in the output character set are included in the output; glyphs that have a probability of less than 75% of matching the output character set are omitted from the output.

To skip embedded fonts using the `formats.ini` file

- Set the following parameters:

  ```
  [pdf_flags]
  skipembeddedfont=TRUE
  embedded_font_threshold=threshold
  ```

  where `threshold` is a value between `0` and `100`. A threshold of `100` skips all embedded font text; a threshold of `0` retains all embedded font text. Set `skipembeddedfont` to **`TRUE`** to enable the `embedded_font_threshold` parameter.

  The default value of `embedded_font_threshold` is `100`. if you set `skipembeddedfont` to **`TRUE`** and do not specify the `embedded_font_threshold` parameter, Filter skips all embedded text.

Use the .NET API

To skip embedded fonts using the .NET API, set the `SkipEmbeddedFont` property. For example:

```
objFilter.SkipEmbeddedFont;
```

Control Hyphenation

There are two types of hyphens in a PDF document:

- A *soft hyphen* is added to a word by a word processor to divide the word across two lines. This is a discretionary hyphen and is used to ensure proper text flow in justified text.
- A *hard hyphen* is intentionally added to a word regardless of the word's position in the text flow. It is required by the rules of grammar and/or word usage. For example, compound words (such as *three-week vacation* and *self-confident*) contain hard hyphens.

By default, KeyView skips the source document's soft hyphens in the Filter output to provide more searchable text content. However, if you want to maintain the document layout, you can keep soft hyphens in the Filter output. To keep soft hyphens, you must enable the soft hyphen flag in `formats.ini` or in the API.

Use the formats.ini File

To keep soft hyphens using the `formats.ini` file, set the following parameter:

```
[pdf_flags]
keepsofthyphen=TRUE
```

Use the .NET API

To keep soft hyphens using the Java API, set the `KeepSoftHyphen` property to **`TRUE`**. For example:

```
objFilter.KeepSoftHyphen = TRUE;
```

Filter Spreadsheet Files

Filter has special configuration options that allow greater control over the conversion of spreadsheet files.

Filter Worksheet Names

Normally, Filter does not extract worksheet names from a spreadsheet because it is assumed the text should not be exposed. You can change this default behavior, and extract worksheet names by adding the following lines to the `formats.ini` file:

```
[Options]
getsheetnames=1
```

Filter Hidden Text in Microsoft Excel Files

Normally, Filter does not filter hidden text from a Microsoft Excel spreadsheet because it is assumed the text should not be exposed. You can change this default behavior, and extract text from hidden rows, columns, and sheets from Excel spreadsheets by adding the following lines to the `formats.ini` file:

```
[Options]
gethiddeninfo=1
```

Specify Date and Time Format on UNIX Systems

In Microsoft Excel you can choose to format dates and times according to the system locale. On Windows, KeyView uses the system locale settings to determine how these dates and times should be formatted. In other operating systems, KeyView uses the U.S. short date format (*mm/dd/yyyy*). You can change this by specifying the formats you wish to use in the `formats.ini` file.

To specify the system date and time format on UNIX systems

- In the `formats.ini` file, specify the following options:
  - `SysDateTime`. The format to use when a cell is formatted using the system format including both the date and the time.
  - `SysLongDate`. The format to use when a cell is formatted using the system long date format.
  - `SysShortDate`. The format to use when a cell is formatted using the system short date format.
  - `SysTime`. The format to use when a cell is formatted using the system time format.

  > **NOTE:**
  > These values cannot contain spaces.

  For example, if you specify `SysDateTime=%d/%m/%Y`, dates and times are extracted in the following format:

  28/02/2008

The format arguments are the same as those for the `strftime()` function. Refer to the following webpage for more information.

http://linux.die.net/man/3/strftime

Filter Very Large Numbers in Spreadsheet Cells to Precision Numbers

Numbers in Microsoft Excel files can now be extracted and written to the output without formatting. By default, numbers are extracted in the format specified by the Excel file (for example, *General, Currency* and *Date*). Spreadsheets might contain cells that have very large numbers in them. Excel displays the numbers in a scientific notation that rounds or truncates the numbers.

To extract numbers without formatting, add the following options in the `formats.ini` file:

```
[Options]

ignoredefnumformats=1
```

Extract Microsoft Excel Formulas

Normally, the actual value of a formula is extracted from an Excel spreadsheet; the formula from which the value is derived is not included in the output. However, KeyView enables you to include the value as well as the formula in the output. For example, if Filter is configured to extract the formula and the formula value, the output might look like this:

```
245 = SUM(B21:B26)
```

The calculated value from the cell is `245` and the formula from which the value is derived is `SUM (B21:B26)`.

> **NOTE:**
> Depending on the complexity of the formulas, enabling formula extraction might result in slightly slower performance.

To set the extraction option for formulas, add the following lines to the `formats.ini` file:

```
[Options]
getformulastring=option
```

where `option` is one of the following:

Option	Description
`0`	Extract the formula value only. This is the default. If formula extraction is enabled, and you want to return to the default, set this option.
`1`	Extract the formula only.
`2`	Extract the formula and the formula value.

If a function in a formula is not supported or is invalid, and option 1 or 2 is specified, only the calculated value is extracted. See Supported Microsoft Excel Functions, below for a list of supported functions.

When formula extraction is enabled, Filter can extract Microsoft Excel formulas that contain the functions listed in Supported Microsoft Excel Functions, below:

Supported Microsoft Excel Functions

=ABS()	=ACOS()	=AND()	=AREAS()
=ASIN()	=ATAN2()	=ATAN2()	=AVERAGE()
=CELL()	=CHAR()	=CHOOSE()	=CLEAN()
=CODE()	=COLUMN()	=COLUMNS()	=CONCATENATE()
=COS()	=COUNT()	=COUNTA()	=DATE()
=DATEVALUE()	=DAVERAGE()	=DAY()	=DCOUNT()
=DDB()	=DMAX()	=DMIN()	=DOLLAR()
=DSTDEV()	=DSUM()	=DVAR()	=EXACT()
=EXP()	=FACT()	=FALSE()	=FIND()
=FIXED()	=FV()	=GROWTH()	=HLOOKUP()
=HOUR()	=ISBLANK()	=IF()	=INDEX()
=INDIRECT()	=INT()	=IPMT()	=IRR()
=ISERR()	=ISERROR()	=ISNA()	=ISNUMBER()
=ISREF()	=ISTEXT()	=LEFT()	=LEN()
=LINEST()	=LN()	=LOG()	=LOG10()
=LOGEST()	=LOOKUP()	=LOWER()	=MATCH()
=MAX()	=MDETERM()	=MID()	=MIN()
=MINUTE()	=MINVERSE()	=MIRR()	=MMULT()
=MOD()	=MONTH()	=N()	=NA()
=NOT()	=NOW()	=NPER()	=NPV()
=OFFSET()	=OR()	=PI()	=PMT()
=PPMT()	=PRODUCT()	=PROPER()	=PV()
=RATE()	=REPLACE()	=REPT()	=RIGHT()
=ROUND()	=ROUND()	=ROW()	=ROWS()
=SEARCH()	=SECOND()	=SIGN()	=SIN()
=SLN()	=SQRT()	=STDEV()	=SUBSTITUTE()

```
=SUM()        =SYD()       =T()          =TAN()
=TEXT()       =TIME()      =TIMEVALUE()  =TODAY()
=TRANSPOSE()  =TREND()     =TRIM()       =TRUE()
=TYPE()       =UPPER()     =VALUE()      =VAR()
=VLOOKUP()    =WEEKDAY()   =YEAR()
```

Filter HTML Files

KeyView can filter comments from HTML documents. To enable comment filtering, you must set a flag in the `formats.ini` file.

The `formats.ini` file is in the `install\`*OS*`\bin` directory, where `install` is the Filter installation directory and *OS* is the name of the operating system.

To enable filtering of comments from HTML files

1. Open the `formats.ini` file in a text editor.
2. Under `[Options]`, set the following flag.

   ```
   GetHTMLHiddenInfo=1
   ```

Filter XML Files

Filter SDK enables you to extract all or selected content from source XML files. You can specify the elements and attributes extracted from a document using the API or an INI file (see Configure Element Extraction for XML Documents, below). Filter detects the following XML formats:

- generic XML
- Microsoft Office 2003 XML (Word, Excel, and Visio)
- StarOffice/OpenOffice XML (text document, presentation, and spreadsheet)

See File Format Detection, on page 166 for more information on format detection.

Configure Element Extraction for XML Documents

When filtering XML files, you can specify which elements and attributes are extracted according to the file's format ID or *root element*. This is useful when you want to extract only relevant text elements, such as abstracts from reports, or a list of authors from an anthology.

A root element is an element in which all other elements are contained. In the XML sample below, `book` is the root element:

```
<book>
  <title>XML Introduction</title>
  <product id="33-657" status="draft">XML Tutorial</product>
  <chapter>Introduction to XML
```

```
      <para>What is HTML</para>
      <para>What is XML</para>
   </chapter>
   <chapter>XML Syntax
      <para>Elements must have a closing tag</para>
      <para>Elements must be properly nested</para>
   </chapter>
</book>
```

For example, you could specify that when filtering files with the root element `book`, the element `title` is extracted as metadata, and only `product` elements with a `status` attribute value of `draft` are extracted. When you extract an element, the child elements within the element are also extracted. For example, if you extract the element `chapter` from the sample above, the child element `para` is also extracted.

Filter SDK defines default element extraction settings for the following XML formats:

- generic XML
- Microsoft Office 2003 XML (Word, Excel, and Visio)
- StarOffice/OpenOffice XML (text document, presentation, and spreadsheet)

These settings are defined internally and are used when filtering these file formats; however, you can modify their values.

In addition to the default extraction settings, you can also add custom settings for your own XML document types. If you do not define custom settings for your own XML document types, the settings for the generic XML are used.

Modify Element Extraction Settings

You can modify configuration settings for XML documents through either the API or the `kvxconfig.ini` file.

Use an Initialization File

To modify the settings for the standard XML document types, or add configuration settings for your own XML document types, follow these steps:

1. Modify the `kvxconfig.ini` file.
2. Use the initialization file when processing the XML file. See Modify Element Extraction Settings in the kvxconfig.ini File, below.

Modify Element Extraction Settings in the kvxconfig.ini File

The `kvxconfig.ini` file contains default element extraction settings for supported XML formats. The file is in the directory `install\`*`OS`*`\bin`, where `install` is the path name of the Filter installation directory and `OS` is the name of the operating system. For example, the following entry defines extraction settings for the Microsoft Visio 2003 XML format:

```
[config3]
eKVFormat=MS_Visio_XML_Fmt
```

```
szRoot=
szInMetaElement=DocumentProperties
szExMetaElement=PreviewPicture
szInContentElement=Text
szExContentElement=
szInAttribute=
```

The following options are available:

Configuration Option	Description
`eKVFormat`	The format ID as detected by the KeyView detection module. This determines the file type to which these extraction settings apply. See File Format Detection, on page 166 for more information on format ID values. If you are adding configuration settings for a custom XML document type, this is not defined.
`szRoot`	The file's root element. When the format ID is not defined, the root element is used to determine the file type to which these settings apply. To further qualify the element, specify its namespace. See Specify an Element's Namespace and Attribute, on the next page.
`szInMetaElement`	The elements extracted from the file as metadata. All other elements are extracted as text. Separate multiple entries with commas. To further qualify the element, specify its namespace, its attributes, or both. See Specify an Element's Namespace and Attribute, on the next page.
`szExMetaElement`	The child elements in the included metadata elements that are not extracted from the file as metadata. For example, the default extraction settings for the Visio XML format extract the `DocumentProperties` element as metadata. This element includes child elements such as `Title`, `Subject`, `Author`, `Description`, and so on. However, the child element `PreviewPicture` is defined in `szExMetaElement` because it is binary data and should not be extracted.

Configuration Option	Description
	You cannot exclude any metadata elements from the output for StarOffice files. All metadata is extracted regardless of this setting. Separate multiple entries with commas. To further qualify the element, specify its namespace, its attributes, or both. See Specify an Element's Namespace and Attribute, below.
`szInContentElement`	The elements extracted from the file as content text. Enter an asterisk (*) to extract all elements including child elements. Separate multiple entries with commas. To further qualify the element, specify its namespace, its attributes, or both. See Specify an Element's Namespace and Attribute, below.
`szExContentElement`	The child elements in the included content elements that are not extracted from the file as content text. Separate multiple entries with commas. To further qualify the element, specify its namespace, its attributes, or both. See Specify an Element's Namespace and Attribute, below.

`szInAttribute`	The attribute values extracted from the file. If attributes are not defined here, attribute values are not extracted.
	Enter the namespace (if used), element name, and attribute name in the following format:
	`namespace:elementname@attributename`
	For example:
	`hpe:division@name`
	Separate multiple entries with commas.

Specify an Element's Namespace and Attribute

To further qualify an element, you can specify that the element exist in a certain namespace and/or contain a specific attribute. To define the namespace *and* attribute of an element, enter the following:

```
ns_prefix:elemname@attribname=attribvalue
```

> **NOTE:**
> Attribute values that contain spaces must be enclosed in quotation marks.

For example, the entry `bg:language@id=xml` extracts a `language` element in the namespace `bg` that contains the attribute name `id` with the value of "`xml`". This entry extracts the following element from an XML file:

```
<bg:language id="xml">XML is a simple, flexible text format derived from
SGML</bg:language>
```

but does not extract:

```
<bg:language id="sgml">SGML is a system for defining markup
languages.</bg:language>
```

or

```
<adv:language id="xml">The namespace should be a Uniform Resource Identifier
(URI).</adv:language>
```

Add Configuration Settings for Custom XML Document Types

You can define element extraction settings for custom XML document types by adding the settings to the `kvxconfig.ini` file. For example, for files that contain the root element `autxml`, we could add the following section to the end of the initialization file:

```
[config101]
eKVFormat=
szRoot=autxml
szInMetaElement=dc:title,dc:meta@title,dc:meta@name=title
szExMetaElement=

szInContentElement=aut:division@name=keyview,aut:division@name=idol,p@style="Headin
g 1"
szExContentElement=
szInAttribute=aut:division@name
```

The custom extraction settings must be preceded by a section heading named `[configN]`, where `N` is an integer starting at 100 and increasing by 1 for each additional file type, as in `[config100]`, `[config101]`, `[config102]`, and so on. The default extraction settings for the supported XML formats are numbered `config0` to `config99`. Currently only `0` to `6` are used.

Since a custom XML document type is not recognized by the KeyView detection module, the format ID is not defined. The file type is identified by the file's root element only.

If a custom XML document type is not defined in the `kvxconfig.ini` file or by the `SetConfigOption` method, then the default extraction settings for a generic XML document are used.

Configure Headers and Footers

You can configure custom header and footer tags for word processing and spreadsheet documents by editing the `formats.ini` file.

To configure headers and footers

1. Open the `formats.ini` file.
2. In the `[Options]` section, add the following items:

```
header_start_tag=HeaderStart
header_end_tag=HeaderEnd
footer_start_tag=FooterStart
footer_end_tag=FooterEnd
```

For example:

```
header_start_tag=<myHeaderTag>
header_end_tag=</myHeaderTag>
footer_start_tag=<myFooterTag>
footer_end_tag=</myFooterTag>
```

> **NOTE:**
> You must encode custom tags in UTF-8.

Tab Delimited Output for Embedded Tables

You can use KeyView to convert embedded tables in Word Processing documents (for example, Microsoft Word) to tab-delimited form, by specifying the following option in the `formats.ini` file:

```
[Options]
TabDelimitedOutput=TRUE
```

This option inserts a tab character between each cell, and a line break between each row. Tab and line break characters in the cells are replaced with spaces.

Exclude Japanese Guide Text

This option prevents output of Japanese phonetic guide text when Microsoft Excel (`.xlsx`) files are processed.

To prevent output of Japanese phonetic guide text

- Set `NoPhoneticGuides` to **`TRUE`** in the `formats.ini` file:

```
[Options]
NoPhoneticGuides=TRUE
```

You can also enable this option programatically when filtering by passing `KVFLT_NOPHONETICGUIDES` to `fpFilterConfig`.

Chapter 5: Sample Programs

This section describes the sample programs provided with Filter SDK.

FilterTestDotNet

The `FilterTestDotNet` sample program calls the following sample code:

- TestExtract—demonstrates the File Extraction interface
- TestFilter—demonstrates the Filtering methods

The source code is in the directory *`install`*`\dotnetapi\sample`, where *`install`* is the path name of the Filter installation directory.

TestExtract

The `TestExtract` code demonstrates the File Extraction interface. The `TestExtract` sample code demonstrates the functionality of the Filtering interface. See TestFilter, on the next page.

The `TestExtract` code demonstrates the following functionality:

- opens a document
- extracts subfiles from a document
- repeats subfile extraction until all subfiles are extracted
- enables you to specify the command-line options listed in Options for TestExtract , below

To run `TestExtract`, type the following at the command line:

`FilterTestDotNet -ex [`*`options`*`] `*`input_file output_file`*

where:

`options` is one or more of the options listed in Options for TestExtract , below.

`input_file` is the path and file name of the source file.

`output_file` is the path and file name of the output file if the source file is not a container file.

Options for TestExtract

Option	Description
`-cr`	Creates a root directory on which a hierarchy can be based. See Create a Root Node, on page 35.
`-c`	Specifies that the subfile directory structure is not created.
`-dr`	Specifies the filter working directory where KeyView binaries are stored. Typically, this is

Options for TestExtract , continued

Option	Description
`binDir`	the `bin` directory.
`-e`	Extracts the subfiles from a source file but does not filter the files after extraction.
`-ed`	Sets the directory to which the subfiles are extracted.
`-f`	Extracts the formatted version of the message body (HTML or RTF) from mail files when possible.
`-id idfile`	Specifies the user ID file used to open a protected PST file.
`-ip`	Runs file extraction in the same process as the calling application (in process). See Run Filter In Process, on page 28.
`-is`	Sets the input as a stream. The default is file.
`-l`	Sets the byte order for Unicode text to Little Endian.
`-lg outfile`	Sets the log file name.
`-m`	Extracts default mail metadata and writes it to the log file. See Extract Mail Metadata, on page 37.
`-nd`	Do not create the subfile directory structure.
`-nh`	Excludes mail header information from the extracted message body text file. See Exclude Metadata from the Extracted Text File, on page 43.
`-os`	Sets the output as a stream. The default is file.
`-p password`	Specifies the password used to open a protected PST file.
`-sc charset`	Sets the character set of the source file. `charset` is a character set defined in the Filter class. See Coded Character Sets, on page 123.
`-tc charset`	Sets the character set of the output file. `charset` is a character set defined in the Filter class. See Coded Character Sets, on page 123.
`-u username`	Specifies the user name used to open a protected PST file.

TestFilter

The `TestFilter` code demonstrates most of the Filtering methods available in the .NET API. The command-line options are listed in Options for FilterTestDotNet -ft1, on the next page.

To run `TestFilter`, type the following at the command line:

`FilterTestDotNet` *`filtermode`* `[`*`options`*`]` *`input_file output_file`*

where:

`filtermode` is one of the options listed in Filter modes, below

`options` is one or more of the options listed in Options for FilterTestDotNet -ft1, below. Options are available for the `-ft1` filter mode only.

`input_file` is the path and file name of the source file.

`output_file` is the path and file name of the generated file. If you do not specify a path, the file is output to the current directory.

Filter modes

Mode	Description
`-ft1`	Filters an input file to an output file.
`-ft2`	Filters an input stream to an output file.
`-ft3`	Filters an input file to an output stream.
`-ft4`	Filters an input stream to an output stream.

Options for FilterTestDotNet -ft1

Option	Description
`-co ooperrorlog`	Enable error logging. See Enable or Disable Error Logging, on page 56. Error logs are not generated when in-process filtering is enabled.
`-cs charset`	Set the character set of the source file. `charset` is a character set defined in the Filter class. See Coded Character Sets, on page 123.
`-ct tempfile`	Specify a temporary directory where temporary files generated by the filtering process are stored. The default is the current working directory. On Windows systems, there is a 64 K size limit to the temporary directory. When the limit is reached, you must either create a new directory or delete the contents of the existing directory; otherwise, you might receive an error message.
`-cx xmlconfigfile`	Filter an XML file by using customized extraction settings defined in the `kvxconfig.ini` file. If you do not enter the full path to the INI file, the program looks for the file in the current working directory. See Filter XML Files, on page 72.
`-d`	Extract the file format information.
`-dr binDir`	Specify the filter working directory where KeyView binaries are stored. Typically, this is the `bin` directory.
`-fto timeout`	Specifies a Filter timeout value in seconds.

Options for FilterTestDotNet -ft1, continued

Option	Description
`-h`	Extract headers and footers, as well as the body text.
`-ht`	Put tags around header and footer data.
`-i filename`	Extract the metadata (summary information) and write it to a file. *filename* is the name of the file to which the metadata is written. See Extract Metadata, on page 58.
`-ia summaryfile`	Extract the document summary information and write it to a summary file, including all metadata for the `pdfsr` reader.
`-im`	If you set this option, text that was deleted from a document with revision tracking enabled is extracted from the document and included in the filtered output. See Extract Deleted Text Marked by Tracked Changes, on page 63.
`-ip`	Run Filter in the same process as the calling application (in process). See Run Filter In Process, on page 28.
`-lo`	Specify that PowerPoint PPT97 and PPTX file text data is output in a logical reading order.
`-ne`	Exclude embedded objects in Microsoft Word files.
`-pdfauto`	The PDF filter determines the paragraph direction (left-to-right or right-to-left) for each PDF page, and then sets the direction accordingly. See Filter PDF Files, on page 64.
`-pdfltr`	Specify that PDF files are output in a logical reading order in left-to-right paragraph direction.
`-pdfrtl`	Specify that PDF files are output in a logical reading order in right-to-left paragraph direction.
`-rc character`	Set a replacement character for characters that cannot be mapped. The default is a question mark (?).
`-tc charset`	Set the character set of the output file. Use the `-getTargetCS` option to determine whether the target character set specified is used in the output file. `charset` is a character set defined in the Filter class. See Coded Character Sets, on page 123.
`-um`	Use MSBLSB byte order. MSBLSB is the “Most Significant Byte Least Significant Byte,” or in other words, the byte order for Big Endian systems (Unicode text only).
`-ul`	Use LSBMSB byte order. LSBMSB is the “Least Significant Byte Most Significant Byte,” or in other words, the byte order for Little Endian systems (Unicode text only).

Options for FilterTestDotNet -ft1, continued

Option	Description
`-ulb`	Generate LSBMSB output with byte order marker (Unicode text only).
`-umb`	Generate MSBLSB output with byte order marker (Unicode text only).
`-embeddedfont`	If you use this option, text that contains embedded fonts is not filtered from PDF documents. See Filter PDF Files, on page 64.

Appendixes

This section lists supported formats, supported character sets, and redistributed files, and provides information on format detection and developing a custom document reader.

Appendix A: Supported Formats

This section lists information about the file formats that can be detected and processed (either filtered, converted, or displayed) by the KeyView suite of products. The KeyView suite includes KeyView Filter SDK, KeyView Export SDK, and KeyView Viewing SDK.

Supported Formats

The tables in this section provide the following information:

- The file formats supported by the Filter API, Export API, Viewing API, and File Extraction API. The supported versions and the format's extension are also listed.

  The formats listed in this section can also be detected by the KeyView format detection module (`kwad`). The Supported Formats (Detected) section lists formats that can be detected, but cannot be filtered, converted, or displayed.
- The file formats for which KeyView can detect and extract the character set and metadata information (properties such as title, author, and subject).

  Even though a file format might be able to provide character set information, some documents might not contain character set information. Therefore, the document reader would not be able to determine the character set of the document. In this case, either the operating system code page or the character set specified in the API is used.
- The document reader used to filter each format.

Key to Support Tables

Symbol	Description
Y	The format is supported. You can extract metadata for this format. You can determine the character set for this format.
N	The format is not supported. You cannot extract metadata for this format. You cannot determine the character set for this format.
P	Partial metadata is extracted from this format. Some non-standard fields are not extracted.
T	Only text is extracted from this format. Formatting information is not extracted.
M	Only metadata (title, subject, author, and so on) is extracted from this format. Text and

Supported CAD Formats

Format	Version	Reader	Extension	Filter	Export	View	Extract	Metadata	Charset	Header/Footer
AutoCAD Drawing	R13, R14, R15/2000, 2004, 2007, 2010, 2013	kpODArdr kpDWGrdr[1]	DWG	Y	Y[2]	Y [3]	N	Y	Y	N

[1]On Windows platforms, kpODArdr is used for all versions up to 2007 and graphic rendering is supported; for later versions, only text extraction is supported through the kpDWGrdr or kpDXFrdr reader.
[2]On non-Windows platforms, graphic rendering is supported through the kpDWGrdr reader for versions R13, R14, R15, and R18 (2004); for other versions, only text extraction is supported.
[3]On non-Windows platforms, graphic rendering is supported through the kpDWGrdr reader for versions R13, R14, R15, and R18 (2004); for other versions, only text extraction is supported.

Supported CAD Formats, continued

Format	Version	Reader	Extension	Filter	Export	View	Extract	Metadata	Charset	Header/Footer
AutoCAD Drawing Exchange	R13, R14, R15/2000, 2004, 2007, 2010, 2013	kpODArdr kpDXFrdr[1]	DXF	Y	Y[2]	Y[3]	N	Y	Y	N
CATIA formats	5	kpCATrdr	CAT[4]	Y	N	N	N	Y	N	N
Microsoft Visio	4, 5, 2000, 2002, 2003, 2007, 2010[5]	vsdsr	VSD	Y	Y	Y	Y[6]	Y	Y	N
		kpVSD2rdr	VSD, VSS VST	Y	Y	Y	N	Y	Y	N
	2013	ActiveX components	VSDM VSSM VSTM VSDX VSSX VSTX	N	N	Y[7]	N	Y	N	N
		kpVSDXrdr	VSDM	Y	Y	Y[4]	Y	Y	Y	N

[1]On Windows platforms, kpODArdr is used for all versions up to 2007 and graphic rendering is supported; for later versions, only text extraction is supported through the kpDWGrdr or kpDXFrdr reader.
[2]On non-Windows platforms, graphic rendering is supported through the kpDXFrdr reader for versions R13, R14, R15, and R18 (2004); for other versions, only text extraction is supported.
[3]On Windows platforms, kpODArdr is used for all versions up to 2007 and graphic rendering is supported; for later versions, only text extraction is supported through the kpDWGrdr or kpDXFrdr reader.
[4]All CAT file extensions, for example CATDrawing, CATProduct, CATPart, and so on.
[5]Viewing and Export use the graphic reader, kpVSD2rdr for Microsoft Visio 2003, 2007, and 2010, and vsdsr for all earlier versions. Image fidelity in Viewing and Export is therefore only supported for versions 2003 and above. Filter uses the graphic reader kpVSD2rdr for Microsoft Visio 2003, 2007, and 2010, and vsdsr for all earlier versions.
[6]Extraction of embedded OLE objects is supported for Filter on Windows platforms only.
[7]Visio 2013 is supported in Viewing only, with the support of ActiveX components from the Microsoft Visio 2013 Viewer. Image fidelity is supported but other features, such as highlighting, are not.

Text Mail (MIME)	n/a	emlsr[3]	various	Y	T	T	Y	Y	Y	N
		mbxsr[4]	various	Y	T	T	Y	Y	Y	N
Transport Neutral Encapsulation Format	n/a	tnefsr	various	N	N	Y	Y	Y	Y	N

[1]This reader supports both clear signed and encrypted S/MIME. KeyView supports S/MIME for PST, EML, MBX, and MSG files.

[2]Uses Microsoft Messaging Application Programming Interface (MAPI). Note that the native PST reader (`pstsr`) works only on Windows, and requires that you have Microsoft Outlook installed. As an alternative, the MAPI reader (`pstnsr`) runs on all platforms, and does not require Microsoft Outlook. For more information on using the native PST reader or the MAPI reader, see the sections 'Use the Native PST Reader (pstnsr) ' and 'Use the MAPI Reader (pstsr)' in Chapter 3.

[3]This reader supports both clear signed and encrypted S/MIME. KeyView supports S/MIME for PST, EML, MBX, and MSG files.

[4]This reader supports both clear signed and encrypted S/MIME. KeyView supports S/MIME for PST, EML, MBX, and MSG files.

Multimedia Formats

Viewing SDK plays some multimedia files using the Windows Media Control Interface (MCI). MCI is a set of Windows APIs that communicate with multimedia devices.

Supported Multimedia Formats

Supported Multimedia Formats, continued

Format	Version	Reader	Extension	Filter	Export	View	Extract	Metadata	Charset	Header/Footer
Windows Video	2.1	MCI	AVI	N	N	Y	N	N	N	N

NOTE:
Depending on the default multimedia player installed on your computer, the View API might not be able to play some supported multimedia formats. To play multimedia files, the View API uses the Windows Media Control Interface (MCI) to communicate with the multimedia player installed on your computer. If the player does not play a multimedia file that is supported by the Viewing SDK, the View API cannot play the file.

If you cannot play a supported multimedia file by using the View API, install a different multimedia player or compressor/decompressor (codec) component.

Presentation Formats

Supported Presentation Formats

Format	Version	Reader	Extension	Filter	Export	View	Extract	Metadata	Charset	Header/Footer

[1]To successfully use this reader, you must set the `KV_YAHOO_ID` environment variable to the Yahoo user ID. You can optionally set the `KV_OTHER_YAHOO_ID` environment variable to the other Yahoo user ID. If you do not set it, "`Other`" is used by default. If you enter incorrect values for the environment variables, erroneous data is generated.

Supported Formats (Detected)

The file formats listed in this section can be detected by the KeyView format detection module (`kwad`), but cannot be filtered, converted, or displayed. The detection module determines a file's format and reports the information to the developer's application.

The formats listed in Supported Formats, on page 84 can be detected as well as filtered, exported, and viewed.

Appendix B: Character Sets

This section provides information on the handling of character sets in the KeyView suite of products, which includes KeyView Filter SDK, KeyView Export SDK, and KeyView Viewing SDK.

Multibyte and Bidirectional Support

The KeyView SDKs can process files that contain multibyte characters. A multibyte character encoding represents a single character with consecutive bytes. KeyView can also process text from files that contain bidirectional text. Bidirectional text contains both Latin-based text which is read from left to right, and text that is read from right to left (Hebrew and Arabic).

Multibyte and bidirectional support, below indicates which character encodings are supported by KeyView for each format.

Multibyte and bidirectional support

Format	Single-byte	Multibyte	Bidirectional
Archive			
7-Zip (7Z)	n/a	n/a	n/a
AD1 Evidence file	n/a	n/a	n/a
ADJ	n/a	n/a	n/a
B1	n/a	n/a	n/a
BinHex (HQX)	n/a	n/a	n/a
Bzip2 (BZ2)	n/a	n/a	n/a
EnCase – Expert Witness Compression Format (E01)	n/a	n/a	n/a
GZIP (GZ)	n/a	n/a	n/a
ISO (ISO)	n/a	n/a	n/a
Java Archive (JAR)	n/a	n/a	n/a
Legato EMailXtender Archive (EMX)	n/a	n/a	n/a

1

Multibyte PDFs are supported, provided the PDF document is created by using either Character ID-keyed (CID) fonts, predefined CJK CMap files, or `ToUnicode` font encodings, and does not contain embedded fonts. See the Adobe website and the Adobe Acrobat documentation for more information. Any multibyte characters that are not supported are displayed using the replacement character. By default, the replacement character is a question mark (?).

To determine the type of font encodings that are used in a PDF, open the PDF in Adobe Acrobat, and select **File > Document Info > Fonts**. If the Encoding column lists Custom or Embedded encodings, you might encounter problems converting the PDF.

2

The text direction in the output file might not be correct.

3

In Export SDK, a bidirectional right-to-left (`RTL`) tag is extracted from this format and included in the direction element (`<dir=RTL>`) of the output.

Coded Character Sets

This section lists which character set you can use to specify the target character set. The coded character sets are enumerated in `kvtypes.h` and defined in the Filter class.

Code Character Sets

Coded Character Set	Description	Can be set as target charset?
KVCS_UNKNOWN	Unknown character set	N
KVCS_SJIS	Japanese (uses multibyte encoding), cp932	Y
KVCS_GB	Simplified Chinese (China, Singapore, Malaysia) cp936	Y
KVCS_BIG5	Traditional Chinese (Taiwan, Hong Kong, Macaw) cp950	Y
KVCS_KSC	Korean, cp949	Y
KVCS_1250	Windows Latin 2 (Central Europe)	Y
KVCS_1251	Windows Cyrillic (Slavic)	Y
KVCS_1252	Windows Latin 1 (ANSI)	Y
KVCS_1253	Windows Greek	Y
KVCS_1254	Windows Latin 5 (Turkish)	Y
KVCS_1255	Windows Hebrew	Y
KVCS_1256	Windows Arabic	Y
KVCS_1257	Windows Baltic Rim	Y
KVCS_1258	Windows Vietnamese	Y
KVCS_8859_1	ISO 8859-1 Latin 1 (Western Europe, Latin America)	Y
KVCS_8859_2	ISO 8859-2 Latin 2 (Central Eastern Europe)	Y
KVCS_8859_3	ISO 8859-3 Latin 3 (S.E. Europe)	Y
KVCS_8859_4	ISO 8859-4 Latin 4 (Scandinavia/Baltic)	Y
KVCS_8859_5	ISO 8859-5 Latin/Cyrillic	Y
KVCS_8859_6	ISO 8859-6 Latin/Arabic	Y
KVCS_8859_7	ISO 8859-7 Latin/Greek	Y
KVCS_8859_8	ISO 8859-8 Latin/Hebrew	Y

Code Character Sets, continued

Coded Character Set	Description	Can be set as target charset?
KVCS_8859_9	ISO 8859-9 Latin/Turkish	Y
KVCS_8859_14	ISO 8859-14	Y
KVCS_8859_15	ISO 8859-15	Y

KVCS_57010	ISCII Gujarathi (x-iscii-gu)	Y[1]
KVCS_57011	ISCII Panjabi (x-iscii-pa)	Y [1]
KVCS_GB18030b2	Reserved for internal use	n/a
KVCS_GB18030	GB18030 (Chinese 4-byte character set)	Y
KVCS_8859_11	ISO 8859-11 (Thai)	Y
KVCS_8859_16	ISO 8859-16 (Latin-10 South-Eastern Europe)	Y
KVCS_ARABICMAC	Arabic Mac (x-mac-arabic)	Y
KVCS_KOI8U	Cyrillic (KOI8U Ukrainian)	Y
KVCS_HZGB2312	The 7-bit representation of GB 2312 / RFC 1842	n/a

1

The character set cannot be forced as output in Export SDK and Viewing SDK because the character set is not supported by the major browsers.

Appendix C: File Formats and Extensions

This section lists the KeyView file format numbers and their associated file extensions.

File Format and Extension Table

This section lists the KeyView file format codes and the file extensions that they are most commonly associated with.

> **NOTE:** This is not a complete list of file extensions. KeyView returns format codes based on file content, which cannot always be predicted from the file extension. Some file extensions might also be associated with multiple format numbers.

KeyView file formats and extensions

Format Name	Format Number	Format Description	Associated File Extension
AES_Multiplus_ Comm_Fmt	1	Multiplus (AES)	PTF
ASCII_Text_Fmt	2	Text	
MSDOS_Batch_ File_Fmt	3	MS-DOS Batch File	BAT
Applix_Alis_Fmt	4	APPLIX ASTERIX	AX
BMP_Fmt	5	Windows Bitmap	BMP
CT_DEF_Fmt	6	Convergent Technologies DEF Comm. Format	
Corel_Draw_Fmt	7	Corel Draw	CDR
CGM_ClearText_ Fmt	8	Computer Graphics Metafile (CGM)	CGM[1]
CGM_Binary_Fmt	9	Computer Graphics Metafile (CGM)	CGM [1]
CGM_Character_ Fmt	10	Computer Graphics Metafile (CGM)	CGM [1]
Word_Connection_ Fmt	11	Word Connection	CN
COMET_TOP_ Word_Fmt	12	COMET TOP

1

This file extension can return more than one format number.

2

MHT, EML, and MBX files might return either format 2, 233, or 395, depending on the text in the file. In general, files that contain fields such as To, From, Date, or Subject are considered to be email messages; files that contain fields such as content-type and mime-version are considered to be MHT files; and files that do not contain any of those fields are considered to be text files.

3

All CAT file extensions, for example CATDrawing, CATProduct, CATPart, and so on.

Appendix D: Extract and Format Lotus Notes Subfiles

This section describes how to create XML templates to alter the appearance of extracted Lotus mail note subfiles so that they maintain the look and feel of the original notes.

Overview

KeyView uses the NSF reader, nsfsr, to extract Lotus database files, and places Lotus mail notes in subfiles. The NSF reader uses a set of default XML templates to extract the notes and apply formatting, thereby approximating the look and feel of the original notes.

In some cases, you might need to customize the XML templates, for instance if your notes contain custom data. In such cases, you can modify the existing XML templates or create your own.

During extraction, the NSF reader loads all XML files in the `NSFtemplates` directory and its subdirectories (except for the `NSFtemplates\images` directory, which is reserved for images). During initialization, the KeyView XML parser verifies the XML templates. If the templates contain any invalid XML, elements, or attributes, initialization fails and errors are recorded in the `nsfsr.log` file.

Customize XML Templates

XML templates are enabled by default. In most cases, the default templates should be sufficient; however, you can customize them or create your own as required.

To customize XML templates for Lotus note extraction

1. Modify the template files in the following directory.

   install`\`*OS*`\bin\NSFtemplates`

   The `main.xml` file must exist in the `NSFtemplates` directory. It is the top-level template file that extracts all subfiles, usually by calling other templates.
2. Make sure that any modifications or additional XML files conform to the supported elements and attributes described in Template Elements and Attributes, on page 155.
3. Extract the Lotus database file.

Use Demo Templates

For testing purposes, you can extract notes by using a set of demo templates, which are provided to demonstrate the proper usage of all the XML elements and attributes, because the default templates do not use all the XML elements.

The demo templates are available at:

*install**OS*\bin\NSFtemplates

To use the demo XML templates

1. In the `formats.ini` file, set the following parameter.

   ```
   [nsfsr]
   UseDemoTemplate=1
   ```

2. In the `main.xml` file, uncomment the following section.

   ```
   <ifini name="UseDemoTemplate" text="1">
     <call file="demo.xml"/>
     <quit/>
   </ifini>
   ```

Use Old Templates

For testing purposes, you can extract notes by using legacy templates, which produce MHTML output. You can generate similar output by disabling the XML templates, but using the old templates enables you to see the XML code and compare it to the standard and demo templates.

To use the old XML templates

1. In the `formats.ini` file, set the following parameter.

   ```
   [nsfsr]
   UseOldTemplate=1
   ```

2. In the `main.xml` file, uncomment the following section.

   ```
   <ifini name="UseOldTemplate" text="1">
     <call file="default_old.xml">
     <quit>
   </ifini>
   ```

Disable XML Templates

For testing purposes, you can disable XML templates; KeyView extracts the notes in MHTML format. You can compare the MHTML output directly by the NSF reader with the MHTML output indirectly by the NSF reader through the XML templates.

To disable XML templates

1. In the `formats.ini` file, set the following parameter.

```
[nsfsr]
ExtractByTemplate=0
```

Template Elements and Attributes

This section lists the valid XML elements and attributes that you can use when creating or modifying templates. See the demo templates for examples.

Conditional Elements

The following table lists the valid conditional elements.

Conditional elements

Element	Description
`<keyview>`	The KeyView XML template container ("root") element
`<if*>`	If the condition from the comparison is true, process the XML. Conditions can be nested up to 25 levels deep. **Attributes** • `name`. (Required) The name of the main item to compare to `item` or `text`. • `item`. (Required if no `text`) The name of the item to compare to the item specified by `name`. • `text`. (Required if no `item`) The text to compare to the item specified by `name`.
`<ifex>, <ifnx>`	If `name` item exists and has a `text` value or not. The Notes item might have a value that cannot be converted to text, such as an image.
`<ifeq>, <ifne>, <iflt>, <ifle>, <ifgt>, <ifge>`	Respectively, if `text` ==, !=, <, >, <=, >, >=. Text comparison uses a case-insensitive string compare.
`<iftdeq>, <iftdne>, <iftdlt>, <iftdle>, <iftdgt>, <iftdge>`	Respectively, if time/date ==, !=, <, >, <=, >, >=. Time/date comparison converts dates to text in local time using the Notes default, `TZFMT_NEVER`, because Notes also sometimes converts fields to text internally. For example: `text="06/30/2005 02:52:04 PM"`
`<iftzeq>, <iftzne>`	Respectively, if the time zone equals or does not equal the comparison `text`, for example `CDT`, `EST`, and so on.

Conditional elements, continued

Element	Description
<ifini>	If the value of the INI option specified in name equals the text value.
<else>	If the condition from the last <if> or <switch> was false, process XML.
<switch>	If a name value exists, process XML. **Attributes** • name. (Required) The name of the main item to compare in <case> subelements.
<case>	If the comparison condition is true, process XML, then stop processing the rest of <switch>. **Attributes** • text. (Required) The text to compare to the name item of <switch>.
<default>	If all <case> conditions were false, process XML. This element must be the last element in <switch>, after all the <case> elements. Any <case> elements after the <default> element are ignored.
<for>	If a name value exists, process XML. Process for each part of the name item. **Attributes** • name. (Required) The name of the main item. • max. (Optional) The maximum index to process. By default, all are processed.
<index>	Output <for> loop index (1-based). <index> is only valid within a <for> element.

Control Elements

The following table lists the valid control elements.

Control Elements

Element	Description
<call>	Call another XML template. You can nest templates up to 10 levels deep. **Attributes** • file. (Required) The template file name. This name must be unique.
<log>	Log message to the NSF log file. **Attributes** • text. (Required) The text to log.

Control Elements, continued

Element	Description
	• `type`. (Optional) The type of log message. The following values are valid: ◦ `ERROR` ◦ `WARN` ◦ `INFO` ◦ `DIAG` (the default option) ◦ `DEBUG` ◦ `DUMP`
`<quit>`	Stop processing the template. Exits without error. **Attributes** • `text`. (Optional) The text to log. • `type`. (Optional) The type of log message. See <log>, on the previous page.
`<stop>`	Stop processing the template. Exits with an `ERROR` log message. **Attributes** • `text`. (Required) The text to log.

Data Elements

The following table lists the valid data elements.

Data elements

Element	Description
`<text>`	Output text. **Attributes** • `name`. (Required if there is no parent) The name of the item to output.
`<rich>`	Output rich text (MHTML). Images are output in the next part or parts of the MHTML, after the first `<HTML>` part. **Attributes** • `name`. (Required if there is no parent) The name of the item to output.
`<body>`	Output the message body in rich text (MHTML). As with <rich>, above, images are output in the next part or parts of the MHTML.
`<form>`	Output the message form (usually `$Body` field) in rich text (MHTML). **Attributes** • `name`. (Required if there is no parent) The name of the item to output.

Data elements, continued

Element	Description
<addr>	Output an address. **Attributes** • name. (Required if there is no parent) The name of the item to output. • type. (Optional) The type of address to output. Set this attribute to CN (Common Name), which is the only supported type.
<name>	Output the name of the last name item, or in other words the current main item. The item must exist.
<format>	Set the default format for <date> and <date_kv>. This element does not set the <text> format. See Date and Time Formats, on the next page for a list of all Notes and KeyView date and time formats and integer values. **Attributes** • format. (Optional. Omit to reset to defaults) The Notes and KeyView date and time format. You can set the following formats: ◦ TD=int. The Time Date format (TDFMT_*) ◦ TS=int. The Time Show format (TSFMT_*) ◦ TT=int. The Time Time format (TTFMT_*) ◦ TZ=int. The Time Zone format (TZFMT_*) ◦ KV=int. The KeyView date and time format where int is an integer value that corresponds to the desired format. Separate multiple formats with commas. For example: format="TD=0,TS=2,TT=1,TZ=1,KV=55"
<date>	Output a Notes date. **Attributes** • name. (Required if there is no parent) The name of the item to output. • format. (Optional) See <format>, above. You can set the following values: ◦ TD ◦ TS ◦ TT ◦ TZ
<date_kv>	Output a KeyView date. **Attributes** • name. (Required if there is no parent) The name of the item to output. • format. (Optional) See <format>, above. You can set the following values: ◦ TZ

Data elements, continued

Element	Description
	◦ KV
<time>	Output a time range, for example 1 hour, 30 minutes. **Attributes** • name. (Required if there is no parent) The item name of the start date or time. • item. (Required) The item name of the end date or time.
<zone>	Output a Notes time zone mnemonic, for example MST. **Attributes** • name. (Required if there is no parent) The name of date item to output.
<zone_utc>	Output a time zone as UTC, for example (UTC-06:00).
<logo>	Output the mail header logo. The image link is included in the output; the actual image is output to a different part of the MHTML subfile.
<image>	Output an image. The image link is included in the output; the actual image is output to the MHTML next part, as with <rich>, on page 157 and <body>, on page 157.
<image_uri>	Output an image URI, in quotation marks. The actual image is output to a different part of the MHTML subfile. **Attributes** • link. (Required if there is no file) The image link, such as a form or title name. For example: • link="StdNotesLtr0" • file. (Required if there is no link) The name of the image file. The file must exist in the ../../templates/images directory. For example: • file="boxcheck.gif"

Date and Time Formats

This section lists the supported Notes and KeyView date and time formats for use with <format>, <date>, and <date_kv>.

Lotus Notes Date and Time Formats

This section lists supported Lotus Notes date and time formats, and the integer values that specify each one.

Lotus Notes date and time formats

Format	Integer Value	Description
TDFMT_FULL	0	(The Notes default) Year, month, and day
TDFMT_CPARTIAL	1	Month and day, year if not this year
TDFMT_PARTIAL	2	Month and day
TDFMT_DPARTIAL	3	Year and month
TDFMT_FULL4	4	Four-digit year, month, and day
TDFMT_ CPARTIAL4	5	Month and day, four-digit year if not this year
TDFMT_ DPARTIAL4	6	Four-digit year and month
TTFMT_FULL	0	(Notes default) Hour, minute, and second
TTFMT_PARTIAL	1	Hour and minute
TTFMT_HOUR	2	Hour
TZFMT_NEVER	0	(Notes default) All time zones are converted to the current time zone
TZFMT_ SOMETIMES	1	Show only when outside the current time zone
TZFMT_ALWAYS	2	Show for all time zones
TSFMT_DATE	0	Date
TSFMT_TIME	1	Time
TSFMT_DATETIME	2	(The Notes default) Date and time
TSFMT_ CDATETIME	4	Date and time, or time today or time yesterday

KeyView Date and Time Formats

This section lists KeyView date and time formats. The KeyView formats use the following syntax:

Month	`Month` = full month name
	`Mon` = abbreviated month name
	`m` = month (number)
	`mm` = two-digit month (leading 0)

Weekday	`Weekday` = full weekday name
	`Wday` = abbreviated weekday name
Year	`yy` = two-digit year
	`yyyy` = four-digit year
Day	`d` = day (number)
	`dd` = two-digit day (leading 0)
Time	`h` = 12-hour
	`H` = 24-hour
	`m` = minutes
	`s` = seconds
	`P` = AM/PM
	`p` = am/pm
Separators	`_` = space
	`c` = comma
	`s` = slash
	`a` = dash
	`o` = dot

KeyView date and time formats

Format	Output	Integer Value
12-Hour and 24-Hour Time Formats		
KVDTF_P	P	1
KVDTF_P_hmm	P h:mm	2
KVDTF_hmm_P	h:mm P	3
KVDTF_P_hhmm	P hh:mm	4
KVDTF_hhmm_P	hh:mm P	5
KVDTF_P_hmmss	P h:mm:ss	6
KVDTF_hmmss_P	h:mm:ss P	7
KVDTF_P_hhmmss	P hh:mm:ss	8
KVDTF_hhmmss_P	hh:mm:ss P	9
KVDTF_Hmm	H:mm	10
KVDTF_HHmm	HH:mm	11

KeyView date and time formats, continued

Format	Output	Integer Value
KVDTF_mmss	mm:ss	12
KVDTF_Hmmss	H:mm:ss	13
KVDTF_HHmmss	HH:mm:ss	14
Numerical Date Formats with Slashes		
KVDTF_mmsdd	mm/dd	15

Appendix E: File Format Detection

This section describes how file formats are detected in Filter SDK.

Introduction

The KeyView format detection module (`kwad`) detects a file's format, and reports the information to the API, which in turn reports the information to the developer's application. If the detected format is supported by the KeyView SDK, the detection module also loads the appropriate structured access layer and document reader for further processing. For a list of supported formats, see Supported Formats, on page 84.

Extract Format Information

You can extract format information from a document by using the `GetDocFormatInfo` method. This method extracts the major format, file class, version, and document attributes, and populates the `DocFormatInfo` class. It returns the format information as a string. The format information that you can extract is listed in the header file `adinfo.h`.

For information on how to translate the extracted format information, see Translate Format Information, on page 169.

Determine Format Support

After the file format is extracted, the detection module uses the `formats.ini` file to determine whether the format is supported by KeyView, and the appropriate structured access layer and reader to load.

The `formats.ini` file is in the directory *`install`*`\`*`OS`*`\bin`, where *`install`* is the path name of the Filter installation directory and *`OS`* is the name of the operating system. It contains the following information:

- Coded format information. To translate this information, see Translate Format Information, on page 169.
- The reader associated with each format. See Determine a Document Reader, on page 170.
- Configuration parameters.
- Locale settings for internal use.

Example formats.ini file entries

```
123=mw
152=xyw
178=wp6
189=mw6
2=af
200=pdf
205=mb
210=htm
251=htm
```

> **NOTE:**
> The `formats.ini` file applies to all formats except graphics. Detection of graphics formats is handled by an internal module named KeyView Picture Interchange Format (KPIF).

Refine Detection of Text Files

During text detection, KeyView analyses the first 1 kB and last 1 kB of data in a document. If less than 10% of that data consists of non-ASCII characters, KeyView detects the document as a text file.

However, depending on the type of documents you are working with, the default settings might not provide the desired level of accuracy. Configuration flags enable you to change the amount of data to read at the end of a file, the percentage of non-ASCII characters permitted in a text file, and whether to use or ignore the file extension to determine the document format.

Change the Amount of File Data to Read

During file detection, KeyView reads characters from the beginning and end of a file—by default, it reads the first and last 1,024 bytes of data. Large text files might contain many irrelevant characters at the end of a file, so KeyView might not accurately detect the file format. You can set a configuration flag to increase the amount of data to read from the end of a file during detection.

To change the amount of data to read during detection

- In the `formats.ini` file, set the following flag in the `detection_flags` section:

  ```
  [detection_flags]
  non_ascii_chars_end_block_size=kB
  ```

  where *kB* is the number of kilobytes to read from the end of the file, from 0 to 10. The default value is 1.

  > **NOTE:**
  > The file size must be greater than the value specified in the flag. If the flag value is greater than the file size, KeyView does not use the flag.

Change the Percentage of Allowed Non-ASCII Characters

By default, if less than 10% of the analyzed data in a document consists of non-ASCII characters, it is detected as a text file. Depending on the type of files that you are working with, changing the default percentage might increase detection accuracy.

To change the percentage of non-ASCII characters allowed in text files

- In the `formats.ini` file, set the following flag in the `detection_flags` section:

  ```
  [detection_flags]
  non_ascii_chars_in_text=N
  ```

  where *N* is the percentage of non-ASCII characters to allow in text files. Files that contain a lower percentage of non-ASCII characters than *N* are detected as text files. The default value is `10`.

Allow Consecutive NULL Bytes in a Text File

By default, if a document contains consecutive `NULL` bytes, it is not detected as text. Depending on the type of files that you are working with, changing the default might increase detection accuracy.

To allow consecutive NULL bytes of ASCII characters in text files

In the `formats.ini` file, set the following flag in the `detection_flags` section:

```
[detection_flags]
ascii_allow_null_bytes=1
```

The default value is 0 (do not allow consecutive NULL bytes).

Use the File Extension for Detection

Sometimes KeyView detects certain file formats, such as CSV, as ASCII because of the content of the documents. In such cases, you can configure KeyView to use the file extension to determine the document format. Using the file extension can improve detection of formats such as CSV, but might not detect text files successfully if they have incorrect file extensions.

To use the file extension for ASCII files during detection

- In the `formats.ini` file, set the following flag in the `detection_flags` section:

  ```
  [detection_flags]
  use_extension_for_ascii=1
  ```

  The default is 0 (do not use the file extension).

Translate Format Information

Format information can include file attributes in the following categories:

- Major format
- File class
- Minor format
- Major version
- Minor version

Not all categories are required. Many formats only include major format and file class, or major format only.

The format information has the following structure:

```
MajorFormat.FileClass.MinorFormat.MajorVersion.MinorVersion
```

For example:

```
81.2.0.9.0
```

Each number in the format information represents a file attribute. The entry `81.2.0.9.0` represents a Lotus 1-2-3 Spreadsheet file version 9.0, where

`81`= Lotus 1-2-3 Spreadsheet (major format)

`2` = Spreadsheet (file class)

`0` = not defined (minor format)

`9` = 9 (major version)

`0` = 0 (minor version)

This example applies to the `formats.ini` file. When extracting format information using the `GetDocFormatInfo` method, the same format is represented as `294.2.9.0`.

> **NOTE:**
> The format values returned from `GetDocFormatInfo` differ from those in `formats.ini` because the former defines a unique ID for each major format, while the latter uses a major version, minor version, and minor format to distinguish between formats.

Distinguish Between Formats

The `DocFormatInfo` class provides a unique ID for each major format. For example, a call to `GetDocFormatInfo` would return `351.1.0` for a Microsoft Word XML format. The major format `351` is unique to this format.

Unlike `DocFormatInfo`, the `formats.ini` file distinguishes between formats by using the major version number. For example, in the `formats.ini` file, a Microsoft Word 2003 XML format is defined as `285.1.0.100.0`. The major format `285` and file class `1` are the same values for generic XML. The major version `100` distinguishes the format as Microsoft Word 2003 XML.

The major version is used to specify the following formats:

- Microsoft Office 2003 XML. This format has the same major format and file class as generic XML (`285.1`). It is distinguished from generic XML by using the following major versions:
  - Word: `100`
  - Excel: `101`
  - Visio: `110`
- The XHTML format has the same major format and file class as HTML (`210.1`). It is distinguished from HTML by using the major version `100`.

Determine a Document Reader

The format detection module uses the `formats.ini` file to determine whether a format is supported, and to determine the reader to use to parse a format. The entries in the `formats.ini` file list each format's coded value, and an abbreviation for the format's reader.

The reader abbreviation is a truncated version of the reader's library name. Adding "`sr`" to the end of an abbreviation creates the name of the reader. For example, this example entry specifies that a Lotus 1-2-3 Spreadsheet file version 9.0 is parsed by the Lotus 1-2-3 filter, `l123sr`:

```
81.2.0.9.0=l123
```

List of Required Files for Redistribution, on page 189 lists the readers provided with KeyView.

Category Values in formats.ini

This section lists the possible category values for format information in the `formats.ini` file. The corresponding values for format information extracted by a call to `GetDocFormatInfo` are listed in the header file `adinfo.h`.

Major Formats

Number	Format	File Class
1	AES Multiplus Comm Format	Word processor
2	ASCII File word processor/MS DOS Batch File format	Word processor
3	Applix Asterix	Word processor
4	Microsoft Windows Bitmap image (BMP)	Raster image
5	Convergent Tech DEF Comm. format	Word processor
6	Corel Draw (CDR)	Vector graphic

Major Formats, continued

Number	Format	File Class
7	Keyword COM.FILE (KSIF)	
8	Computer Graphics Metafile (CGM)	Vector graphic

1 If the major version is 100, the file format is XHTML.

2 The major version determines whether the Microsoft Office XML file is a Word, Excel or Visio document. The major version for each format is as follows:
Word: 100
Excel: 101
Visio: 110

Appendix F: List of Required Files for Redistribution

This section lists the Filter files that can be redistributed in your applications under the licensing agreement. These files are in the directory *install**OS*\bin, where *install* is the path name of the Filter installation directory and *OS* is the name of the operating system.

> **NOTE:**
> On Windows systems, the libraries are `.dll` files. On UNIX systems, the libraries are `.so`, `.a`, or `.sl` files.

Core Files

The following core files can be redistributed with your application.

File	Description
`formats.ini`	Initialization file. For more information on this file, see Determine Format Support, on page 166.
`FilterDotNet.*`	Required by .NET API.
`KeyViewFilter.*`	Required by the Java API.
`kpifcnvt.*`	For presentation graphics, converts from one picture format to another.
`kpifutil.*`	Utility for handling the internal picture interchange format for presentation graphics.
`kvxtract.*`	File Extraction API.
`kvfilter.*`	Filter API.
`kvolefio.*`	Embedded OLE object writer.
`kvutil.*`	Internal KeyView utility functions.
`kvxpgsa.*`	Interface between presentation readers and `kvfilter`. Required to extract metadata from AutoCAD files.
`kvxsssa.*`	Interface between spreadsheet readers and `kvfilter`.
`kvxwpsa.*`	Interface between word processing readers and `kvfilter`.
`kwad.*`	File auto-recognition module.
`txtcnv.*`	Converter for document token stream.

Support Files

The following support files can be redistributed with your application.

File	Description
bentofio.*	Required by l123sr and kpprzrdr.
cbmap.map	Character mappings for Adobe Portable Document Format (PDF).
chartbls.ux	Character mappings.
chmdll.*	Required by chmsr.
kppng.*	Required for ZLIB decompression.
kvxconfig.ini	Contains element extraction settings for XML files.
kvoop.*	Required for out-of-process filtering.
kvthread.*	Required for multithreaded out-of-process filtering.
kv.lic	Contains license information for KeyView products. This file is opened and validated when a KeyView API is used.
MSVCP60.*	Microsoft Visual C++ Runtime library V6.0.
msvcrt.*	Microsoft Visual C Runtime library.
wpmap.*	Extended character mapping for WordPerfect and Corel Presentation.
xmlsh.*	Contains a library of content handlers for each XML file type. Required by the Expat XML parser.

Document Readers

The following readers can be redistributed with your application.

File	Description
ad1sr.*	AD1 Evidence file reader
afsr.*	ASCII reader
aiffsr.*	Audio Interchange Format File (AIFF) reader
asfsr.*	Advanced Systems Format reader
assr.*	Applix Spreadsheet reader
awsr.*	Applix Word reader

File	Description
bl1sr.*	B1 archive reader
bkfsr.*	Microsoft Backup File reader
bmpsr.*	Windows bitmap (BMP) reader
bzip2sr.*	Bzip2 reader
cabsr.*	Microsoft Cabinet format reader
cebsr.*	Founder Chinese E-paper Basic reader
chmsr.*	Microsoft Compiled HTML Help reader
csvsr.*	Comma-Separated Values reader
dbfsr.*	dBase Database reader
dbxsr.*	Microsoft Outlook Express DBX reader
dcasr.*	Document Content Architecture/Revisable Form Text (DCA/RFT) reader
dcmsr.*	Digital Imaging and Communications in Medicine (DICOM) reader
difsr.*	Data Interchange Format reader
dmgsr.*	Mac Disk Copy Disk Image File reader
dw4sr.*	DisplayWrite reader
dxlsr.*	Domino XML Language reader
emlsr.*	Microsoft Outlook Express (EML) reader. This is used to filter EML files when the MBX reader is not licensed.
emxsr.*	Legato EMailXtender (EMX) reader
encasesr.*	Expert Witness Compression Format (EnCase) v6 reader
encase2sr.*	Expert Witness Compression Format (EnCase) v7 reader
entsr.*	Microsoft Entourage Database Format reader
epubsr.*	Open Publication Structure eBook reader
foliosr.*	Folio Flat File reader
gifsr.*	Graphics Interchange Format (GIF) reader
gwfssr.*	GroupWise FileSurf reader
hl7sr.*	Health level7 reader (metadata only)
htmsr.*	HTML and XHTML reader

File	Description
hwpsr.*	Hangul 97 reader
hwposr.*	Hangul 2002, 2005, 2007 reader
ichatsr.*	Apple iChat Log reader
icssr.*	Microsoft Outlook iCalendar reader
isosr.*	ISO-9660 CD Disc Image Format reader
iwwpsr.*	Apple iWork Pages reader
iwsssr.*	Apple iWork Numbers reader
jp2000sr.*	JPEG 2000 metadata reader
jpgsr.*	JPEG metadata reader
jtdsr.*	JustSystems Ichitaro reader
kpagrdr.*	Applix Presentations reader
kpCATrdr.*	CATIA format reader
kpcgmrdr.*	Computer Graphics Metafile reader
kpDWGrdr.*	AutoCAD Drawing format reader
kpDXFrdr.*	AutoCAD Drawing Exchange format reader
kpemfrdr.*	Enhanced Metafile reader
kpGFLrdr.*	Omni Graffle reader
kpgifrdr.*	Graphic Interchange Format (GIF) reader
kpIWPGrdr.*	Apple iWork Keynote reader
kpmsordr.*	Microsoft Office Drawing Objects (office 97, 2000, and XP) reader
kpODArdr.*	AutoCAD reader (Windows only)
kpodfrdr.*	Oasis Open Document Format presentation (ODP) reader
kpONErdr.*	Microsoft OneNote reader
kpp40rdr.*	Microsoft PowerPoint PC 4.0 and PowerPoint Mac reader
kpp95rdr.*	Microsoft PowerPoint 95 reader
kpp97rdr.*	Microsoft PowerPoint 97 and higher reader
kppctrdr.*	Macintosh Quick Draw Picture (PICT) reader
kppicrdr.*	Pictor PC Paint (PIC) reader

File	Description
kpppxrdr.*	Microsoft PowerPoint XML reader 2007
kpprerdr.*	Lotus Freelance Graphics for Windows V2.0 reader
kpprzrdr.*	Lotus Freelance Graphics 96/97/98 reader
kpshwrdr.*	Corel Presentations reader
kpugrdr.*	Unigraphics (UG) NX reader
kpwg2rdr.*	WordPerfect Graphics 2 reader
kpwmfrdr.*	Windows Metafile reader
kpwpgrdr.*	WordPerfect Graphics 1 reader
kpXFDLrdr.*	Extensible Forms Description Language reader
kvgzsr.*	GZIP reader
kvhqxsr.*	BinHex reader
kvzeesr.*	UNIX Compress reader
l123sr.*	Lotus 123 v96/97/98 reader
lasr.*	Lotus AMI Pro reader
ltbenn30.dll	Lotus Word Pro support (supported on Windows x86 platform only)
ltscsn10.dll	Lotus Word Pro support (supported on Windows x86 platform only)
lwpapin.dll	Lotus Word Pro support (supported on Windows x86 platform only)
lwppann.dll	Lotus Word Pro support (supported on Windows x86 platform only)
lwpsr.dll	Lotus Word Pro reader (supported on Windows x86 platform only)
lzhsr.*	Microsoft Compression Folder reader
macbinsr.*	MacBinary reader
mbsr.*	Microsoft Word Macintosh reader
mbxsr.*	Mailbox (MBX) and Microsoft Outlook Express (EML) reader[1]
mdbsr.*	Microsoft Access reader
mhtsr.*	MIME HTML reader
mifsr.*	Adobe Maker Interchange reader

[1]This reader is an advanced feature and is sold and licensed separately from KeyView Filter SDK. See License Information, on page 17

File	Description
misr.*	Microsoft Word 2 reader
mp3sr.*	MP3 reader for metadata extraction reader
mpeg4sr.*	MPEG-4 Audio file reader
mppsr.*	Microsoft Project reader
msgsr.*	Microsoft Outlook (MSG) reader
mspubsr.*	Microsoft Publisher reader
msw6sr.*	Microsoft Works 6 and 2000 reader
mswsr.*	Microsoft Works V1 and 2 reader
multiarcsr	ARJ Reader
mw6sr.*	Microsoft Word 95 reader
mw8sr.*	Microsoft Word 97, 2000, and XP reader
mwsr.*	Microsoft Word for DOS and Microsoft Write reader
mwssr.*	Microsoft Works Spreadsheet reader
mwxsr.*	Microsoft Word 2007 XML reader

Appendix G: Develop a Custom Reader

This section describes how to develop a reader for a format not supported by KeyView.

Introduction

The Filter SDK enables you to write custom readers for formats not directly supported by KeyView. A reader is required to parse the file format and generate a KeyView token stream, which represents the content and format of the document. Filter can then use this token stream to generate a text version of the original document. The readers interact with a structured access layer and a writer to generate a text file in Filter, an HTML file in HTML Export, an XML file in XML Export, and a near-to-original view of the document in the Viewing SDK.

The complexity of a custom reader depends on the file format used by the source document type. A simple reader extracts only the textual content, but ignores formatting and all other non-textual content. Readers of increasing complexity must address one or more of the following:

- formatting (including fonts, foreground and background colors, paragraph borders and shading, character and paragraph styles)
- tables
- lists
- headers
- footers
- footnotes
- endnotes
- graphics
- bookmarks to internal links
- hyperlinks to external documents or webpages
- other structures, such as a table of contents or index

Even a simple reader might have to parse the following components of a document:

- word processing commands or tags
- encrypted or encoded text
- multiple character sets
- text modified, but retained within the file
- text displayed in an order other than its physical occurrence within the source file

It is very important to fully understand the file specification for the file format used by the document. This is essential in determining how to parse the source file and generate a token stream that accurately and effectively represents the original document.

Within Filter, the custom reader must interact with a structured access layer and the format detection API, which in turn interacts with the top-level API. For a description of the Filter architecture, see Architectural Overview, on page 21.

The custom reader must have a module definition file (`*.def`) that defines the exported API function calls. In addition, the `formats.ini` file must be modified to identify the custom reader and its associated format detection function.

See the source code for the sample custom reader (`utf8sr`), which parses plain text files encoded in UTF-8. The source code is in the directory *`install`*`/samples/utf8sr`, where *`install`* is the path name of the Filter installation directory.

How to Write a Custom Reader

Two include files define the requirements for a custom reader: `kvcfsr.h` and `kvtoken.h`. The definitions of the KeyView tokens are in `kvtoken.h`. For more information on tokens, see Token Buffer, on the next page. The file `kvcfsr.h` defines two structures: `TPReaderInterface` and `adTPDocInfo`.

The `TPReaderInterface` structure defines the API functions implemented by the custom reader. For basic readers, only the first four functions must be implemented. These functions are called by the structured access layer to parse the source file and generate the token stream.

All readers must be threadsafe. This means that global variables must not be used. To pass information between functions, it is necessary to define a "global" context structure that stores all information required throughout the life of the DLL. The initial parameter of all but one of the `TPReaderInterface` functions is a pointer to a global context structure defined for the custom reader.

The `adTPDocInfo` structure defines the information required for the format detection API, which associates the custom reader with the required file format.

Naming Conventions

Use the following naming conventions for functions and files:

- The initial letters of the custom reader file name should identify the file format being parsed. For example, `pdf` for Adobe PDF files, `rtf` for RTF files, and `xls` for Microsoft Excel files. In the examples in this appendix, this is represented by `xxx`.
- The name of the shared library must end with the letters `sr`.
- The name of the exported functions in the module definition file must be `xxxGetReaderInterface` and `xxxsrAutoDet`.

> **NOTE:**
> The letters `sr` are excluded from `xxxGetReaderInterface`, but are included in `xxxsrAutoDet`.

Basic Steps

The basic steps for developing a custom reader are as follows.

To develop a custom reader

1. Design the global context structure.
2. Write the basic API functions:
   - xxxAllocateContext()
   - xxxInitDoc()
   - xxxFillBuffer()
   - xxxFreeContext()
   - xxxCharSet()
   - xxxsrAutoDet()

   From within the `xxxFillBuffer()` function, it is necessary to call other functions that repeatedly read a chunk of a source file, parse the chunk, and generate a token stream until the entire source file is processed.
3. Map all but the last function to the `TPReaderInterface` structure.
4. Write the module definition file (`*.def`), exporting the reader interface and format detection functions.
5. Modify the `formats.ini` file to identify the custom reader and its associated format detection function. See xxxsrAutoDet(), on page 209. For example, the following lines would be added to the `[Formats]` section of the `formats.ini` file for the UTF-8 reader:

   ```
   456.1.0.0=utf8
   [CustomFilters]
   1=utf8sr
   ```

Token Buffer

Filter technology parses the native file structure to generate an intermediate stream called a *token buffer*. The token buffer consists of multiple sequences of tokens, which are defined in `kvtoken.h` and listed below.

```
#define KVT_TEXT         0x00 /* PutText() */
#define KVT_PARAINFO     0x01 /* SetParaInfo() */
#define KVT_SETTABS      0x02 /* SetTabs() */
#define KVT_TAB          0x03 /* Tab() */
#define KVT_MODE         0x04 /* SetMode() */
#define KVT_PARASPACE    0x05 /* SetParaSpace() */
#define KVT_ROWDEFN      0x06 /* DefineRow(), EndTable() */
#define KVT_COLUMNS      0x07 /* StartColumns(), etc. */
#define KVT_CELLSTART    0x08 /* NextCell() */
#define KVT_BITMAP       0x09 /* Reserved for annotations. */
#define KVT_PAGEOBJ      0x0A /* PutHeader(), PrintPage(), etc.*/
```

```
#define KVT_NOOP         0x0B /* Just skip a BYTE. */
#define KVT_PAGE_BREAK   0x0C /* PageBreak() */
#define KVT_PARA_BREAK   0x0D /* ParaEnd() */
#define KVT_LINE_BREAK   0x0E /* LineBreak() */
#define KVT_SET_FONT     0x0F /* SetFont() */
#define KVT_PAGE         0x10 /* SetPageInfo() */
#define KVT_HOTSPOT      0x11 /* StartHotSpot() */
#define KVT_LINESPACE    0x12 /* SetLineSpacing() */
#define KVT_COLOR        0x13 /* VESetTextColor(),VESetBkColor()*/
#define KVT_PICTURE      0x14 /* PutPicture() */
#define KVT_CELLMERGE    0x15 /* MergeCells() */
#define KVT_RULE         0x16 /* HorzRule() */
#define KVT_PATTERN      0x17 /* StartPattern(), etc. */
#define KVT_BORDER       0x18 /* StartParaBorder(), etc. */
#define KVT_HEADING      0x19 /* PutParaHeading() */
#define KVT_LISTING      0x1A /* StartList(), etc. */
#define KVT_CHARSET      0x1B /* SetCharSet() */
#define KVT_STYLE        0x1C /* PutCharStyle(), PutParaStyle()*/
#define KVT_BIDI         0x1D /* Set Bidirectional text */
#define KVT_LOCALE       0x1E /* Set locale of a document */
#define KVT_ZONE         0x1F /* StartZone(), EndZone() */
#define KVT_POSITION     0x20 /* SetPosition(), etc. */
#define KVT_AUTOREC      0x21 /* Reserved for Internal Use */
#define KVT_METADATA     0x22 /* Rsserved for Internal Use */
#define KVT_BYTEORDER    0x23 /* SetByteOrder() */
#define KVT_PARASPACEAUTO 0x24 /* SetParaSpaceAuto() */
#define KVT_ATTACH        0x25 /* PutAttachment() */
#define KVT_TOCPRINTIMAGE 0x26 /* StartTOCPrintImage(), etc. */
#define KVT_STREAM        0x27 /* PutStream(),Reserved */
#define KVT_REVISIONMARK  0x28 /* StartRevisionMark(),
EndRevisionMark(), SetRMAuthor(), SetRMDateTime() */
#define KVT_DOCXTRINFO    0x29 /* SetDocXtrInfo() */
#define KVT_PCTEMDFT      0x30 /* SetPctEmdFt() */
```

A token is a single-byte identifier that corresponds to attributes in a document. Each token has one or more associated macros that provide detailed information about an attribute. Many of these tokens define components of the document, such as page margins, line indentation, and foreground and background color. Collectively, these are referred to as the *state* of the document. This state changes as the document is parsed.

Macros

Some of the macros are simple while others are complicated. An example of a simple macro is `ParaEnd (pcBuf)` which terminates the current paragraph.

```
#define ParaEnd(pcBuf)                                  \
        {                                               \
            *pcBuf++ = KVT_PARA_BREAK;                  \
```

```
            KVT_PUTINT(pcBuf, KVTSIZE_PARA_BREAK);      \
        }
```

In Filter SDK, this generates an `0x0d`, `0x0a` pair of bytes on a Windows machine. In HTML Export this can generate a `<p style="…">` element, depending on the value of other paragraph attributes.

One of the more complicated macros is `PutPictureEx()`.

```
#define PutPictureEx(pcBuf, lpszKey, cx, cy, flags,             \
             scaleHeight, scaleWidth,                           \
             cropFromL, cropFromT, cropFromR, cropFromB,        \
             anchorHorizontal, anchorVertical, offsetX, offsetY)\
          {                                                     \
             PutPic(pcBuf, lpszKey, cx, cy, flags,              \
             scaleHeight, scaleWidth,                           \
             cropFromL, cropFromT, cropFromR, cropFromB,        \
             anchorHorizontal, anchorVertical, offsetX, offsetY,\
             180, 0, 180, 0, -1, 0, 0, 0, 0)                    \
          }
```

You can generate a representation of the token stream by running `filtertest.exe` with the `-d` command-line option. This stream does not include the tokens generated for headers or footers. The `filtertest.exe` is in the directory *`install`*`\samples\utf8\bin`, where *`install`* is the path name of the Filter installation directory.

Reader Interface

All custom readers use the reader interface defined in `kvcfsr.h`. The members of this structure are:

```
fpAllocateContext()
fpInitDoc()
fpFillBuffer()
fpFreeContext()
fpHotSpothit()
fpGetSummaryInfo()
fpOpenStream()
fpCloseStream()
fpGetURL()
fpGetCharSet()
```

> **NOTE:**
> `fpHotSpothit()` and `fpGetURL()` are currently reserved and must be `NULL`.

Function Flow

The structured access layer calls the functions as follows:

1. `fpAllocateContext()` is called and returns a pointer to the global context structure.

2. After further processing within the structured access layer, `fpInitDoc()` is called. This function performs all required initialization for the global context structure and then returns control to the structured access layer.
3. After further processing within the structured access layer, the `fpFillBuffer()` function is called repeatedly until the document is completely parsed.
4. Finally, `fpFreeContext()` is called. This function frees all memory allocated within the custom reader and then returns control to the structured access layer.

- Functions, on page 209

Example Development of fffFillBuffer()

The following is an example of how the `fpFillBuffer()` function in `foliosr` could be developed. The example demonstrates how the code changes as limitations of the implementation are identified. With each implementation, code revisions are shown in bold.

Implementation 1—fpFillBuffer() Function

```
/*****************************************************************
*Function: fffFillBuffer()
*Summary: Read fff input from stream and parse into kvtoken.h codes
*****************************************************************/
int pascal _export fffFillBuffer(
    void    *pCFContext,
    BYTE    *pcBuf,
    UINT    *pnBufOut,
    int    *pnPercentDone,
    UINT    cbBufOutMax )
{
    BOOL bRetVal;
    TPfffGlobals *pContext = (TPfffGlobals *)pCFContext;
    pContext->pcBufOut = pcBuf;
    fffReadSourceFile(pContext);
    bRetVal = fffProcessBuffer(pContext, pcBuf);
    *pnPercentDone = (int)(pContext->unTotalBytesProcessed *
    (UINT)100 / pContext->unFileSize);
    *pnBufOut = (UINT)(pContext->pcBufOut - pcBuf);
    return (bRetVal ? KVERR_Success : KVERR_General);
}
```

The parameters in `fffFillBuffer()` are as follows:

Parameter	In/Out	Description
`pCFContext`	In	A pointer to the context structure of the custom reader.
`pcBuf`	In/Out	A pointer to the token output buffer.

Parameter	In/Out	Description
pnBufOut	Out	A pointer to the number of bytes written to the output buffer.
pnPercentDone	Out	A pointer to the percentage complete.
cbBufOutMax	In	The maximum number of bytes that the token output buffer can hold.

Structure of Implementation 1

1. The local variable pContext is set to the address of the pCFContext void pointer, cast to a pointer to the global context structure for the reader. This provides access to all members of this structure.
2. After setting the pContext variable, a call is made to read the source file.
3. Next, a call is made to fffProcessBuffer(). The second parameter in the call is a pointer to the token output buffer. If this call fails, usually because of memory allocation errors, it returns FALSE.
4. The percentage complete is calculated.
5. The number of BYTES written to the token output buffer is calculated. This is based on the value of pContext->pcBufOut, which is increased each time a token is written to the buffer.
6. The function returns to the structured access layer.
7. Subsequent calls to fffFillBuffer() are made by the structured access layer until the percentage complete is 100.

Problems with Implementation 1

- There is a limit to the size of the token output buffer, typically 4 KB. If fffProcessBuffer() generates a token stream larger than this, there is a memory overflow. If fffProcessBuffer() generates a small token stream and the entire file has not been read, the output token buffer is underutilized.
- It might not be possible to process the entire input buffer from the source file because of boundary conditions. An example of a "boundary condition" is when the input buffer terminates part way through a control sequence in the original document. Another file read operation is required before the complete control sequence can be parsed.
- This function might be interrupted by other calls from the structured access layer to process headers, footers, footnotes, and endnotes, or to retrieve the document summary information. This can cause values of variables in the global context to change, and the source file to be repositioned.

Implementation 2—Processing a Large Token Stream

Implementation 2 addresses the problem of processing a token stream that is larger than the output buffer size limit.

```
/*****************************************************************
* Function:   fffFillBuffer()
* Summary:    Read fff input from stream and parse into kvtoken.h codes
*****************************************************************/
int pascal _export fffFillBuffer(
```

```
    void    *pCFContext,
    BYTE    *pcBuf,
    UINT    *pnBufOut,
    int    *pnPercentDone,
    UINT    cbBufOutMax )
{
    BOOL bRetVal  = TRUE;
    TPfffGlobals *pContext = (TPfffGlobals *)pCFContext;
    pContext->pcBufOut      = pcBuf;
    pContext->cbBufOutMax   = 9 * cbBufOutMax / 10;  /* Process the portion of the
fff file that is in the input buffer but do   * not return from the fffFillBuffer()
function unless the output buffer is   * at least 90% full. If any of the memory
allocations fail during the   * execution of fffProcessBuffer(), bRetVal will be
set to FALSE, resulting   * in this conversion failing "gracefully".
                */
    do

{
        if( pContext->bBufOutFull )

{
            pContext->bBufOutFull = FALSE;
        }
        else

{
            fffReadSourceFile(pContext);
        }
        bRetVal = fffProcessBuffer(pContext, pcBuf);
        *pnPercentDone = (int)(pContext->unTotalBytesProcessed *
        (UINT)100 / pContext->unFileSize);
    }while( bRetVal && !pContext->bBufOutFull && *pnPercentDone < 100 );
    *pnBufOut = (UINT)(pContext->pcBufOut - pcBuf);
    return (bRetVal ? KVERR_Success : KVERR_General);
}
```

Structure of Implementation 2

1. `cbBufOutMax` is used to set `pContext->cbBufOutMax`. This is used in `fffProcessBuffer()` to monitor how full the token output buffer becomes as the source file is processed.
2. When the source file input buffer has been processed, `fffProcessBuffer()` returns, and the percentage complete is calculated.
3. If the token output buffer is not filled to a value greater than `pContext->cbBufOutMax`, `pContext->bBufOutFull` remains set to **`FALSE`**, and if the percentage complete is less than 100, the `do-while` loop is re-entered without returning from this function to the structured access layer. There is another call to `fffReadSourceFile()`, followed by `fffProcessBuffer()`.

4. When the token output buffer is filled to a value greater than `pContext->cbBufOutMax`, `pContext->bBufOutFull` is set to **TRUE**. In this case, the `do-while` loop ends, the number of bytes written to the token output buffer is calculated, and control returns to the structured access layer.
5. The structured access layer continues to make calls to `fffFillBuffer()` until the entire source file is processed.
6. Each time the structured access layer calls `fffFillBuffer()`, another empty token output buffer is provided for the custom reader to use.
7. If the previous call to `fffFillBuffer()` exited because the previous token output buffer exceeded allowable capacity, `pContext->bBufOutFull` is reset to **FALSE** and no call is made to read the next buffer from the input source file.

Problems with Implementation 2

- It might not be possible to process the entire input buffer from the source file because of boundary conditions.
- This function might be interrupted by other calls from the structured access layer to process headers, footers, footnotes, or endnotes, or to retrieve the document summary information. This can cause values of variables in the global context to change, and the source file to be repositioned.

Boundary Conditions

A boundary condition can result from many situations arising from input file processing. For example, the input buffer might end with an incomplete command. In Folio flat files, this could be an incomplete element. In other word processing documents, a boundary condition might result from an incomplete control sequence, a split double-byte character, or a partial UTF-7 or UTF-8 sequence. These can be handled jointly by `fffProcessBuffer()`, which must detect the boundary condition, and `fffReadSourceFile()`.

The following example shows partial code used in `fffReadSourceFile()`:

```
/*************************************************************
 *
 * Function:    fffReadSourceFile()
 *
 *************************************************************/
int pascal fffReadSourceFile(TPfffGlobals *pContext)
{
    int nBytes;
    /* Transfer remaining data to beginning of buffer prior to next read */
    if( pContext->nResidualBytes )
    {
        memcpy(pContext->cInputBuf, pContext->pcBufIn, pContext->nResidualBytes);
    }
    /* Read from file, without over-writing any text from the previous buffer */
    nBytes = (*pContext->pIO->kwReadFunc)(pContext->pIO,
            pContext->cInputBuf + pContext->nResidualBytes,
            BUFFERSIZE - pContext->nResidualBytes);
    /* Update input buffer control parameters */
```

```
    pContext->unTotalBytesRead += (UINT)nBytes;
    pContext->pcBufIn = pContext->cInputBuf;
    pContext->pcBufInMax = pContext->pcBufIn + pContext->nResidualBytes + nBytes;
    pContext->nResidualBytes = 0;
    return nBytes;
}
```

If `fffProcessBuffer()` is unable to process the entire input source file buffer, it sets the value for `pContext->nResidualBytes`. When the next call to `fffReadSourceFile()` is made, any residual bytes are copied to the beginning of the input source file buffer, and the number of bytes to be read is reduced to make sure that this buffer does not overflow.

A good way to test the code for boundary conditions is to vary the size of `BUFFERSIZE` and make sure that the results remain consistent.

> **NOTE:**
> With `ReadSourceFile()`, the source file can be read by calls to retrieve header or footer information. If this occurs, the value for `pContext->unTotalBytesRead` is incorrect.

Implementation 3—Interrupting Structured Access Layer Calls

Implementation 3 addresses the problem of boundary conditions and interrupting calls from the structured access layer.

```
/*****************************************************************************
* Function:   fffFillBuffer()
* Summary:    Read fff input from stream and parse into kvtoken.h codes
*****************************************************************************/
int pascal _export fffFillBuffer(
    void    *pCFContext,
    BYTE    *pcBuf,
    UINT    *pnBufOut,
    int    *pnPercentDone,
    UINT    cbBufOutMax )
{
    double dTotalBytesProcessed, dFileSize;
    BOOL bRetVal = TRUE;
    TPfffGlobals *pContext = (TPfffGlobals *)pCFContext;
    pContext->pcBufOut = pcBuf;
    pContext->cbBufOutMax = 9 * cbBufOutMax / 10;
/* Process the portion of the fff file that is in the input buffer but do
* not return from the fffFillBuffer() function unless the output buffer is
* at least 90% full. If any of the memory allocations fail during the
* execution of fffProcessBuffer(), bRetVal will be set to FALSE, resulting
* in this conversion failing "gracefully". */
    do
    {
         if( pContext->bBufOutFull )
        {
            pContext->bBufOutFull = FALSE;
```

```
        }
         else
        {
            fffReadSourceFile(pContext);
        }
         bRetVal = fffProcessBuffer(pContext, pcBuf);
         if( pContext->bHeaderCompleted )

{
            *pnPercentDone = 100;
            pContext->bHeaderCompleted = FALSE;
        }
         else if( pContext->bFooterCompleted )

{
            *pnPercentDone = 100;
            pContext->bFooterCompleted = FALSE;
        }
         else

{
            if( pContext->unTotalBytesProcessed >= pContext->unFileSize )
            {
                *pnPercentDone = 100;
            }
            else if( pContext->unFileSize < FFF_MAX_ULONG )
            {
                *pnPercentDone = (int)(pContext->unTotalBytesProcessed *
    (UINT)100 / pContext->unFileSize);
            }
             else

{
                dTotalBytesProcessed = pContext->unTotalBytesProcessed;
               dFileSize = pContext->unFileSize;
                *pnPercentDone = (int)(dTotalBytesProcessed * 100 / dFileSize);
            }
    }
    }while( bRetVal && !pContext->bBufOutFull && *pnPercentDone < 100 );
    *pnBufOut = (UINT)(pContext->pcBufOut - pcBuf);
    return (bRetVal ? KVERR_Success : KVERR_General);
}
```

Structure of Implementation 3

- The most significant change in Implementation 3 is the addition of the code that checks whether the processing of the header or footer is complete. The variables for `pContext->bHeaderCompleted` and `pContext->bFooterCompleted` are set to **TRUE** in `fffProcessBuffer()` when a header or footer is

processed and the end of that portion of the document is reached.

- The other piece of code added in Implementation 3 is unique to `foliosr`. Folio files can be 50 MB or larger. Therefore, an unsigned integer is too small to accurately calculate the percentage complete. If the file size exceeds `FFF_MAX_ULONG`, which is defined as `(UINT)(0xFFFFFFFF / 0x64)`, the doubles are used for that calculation.
- Prior to returning, the token output buffer is as full as possible and never overflows. The minimum number of calls is made.

Development Tips

- Avoid unnecessary initialization.

  The context variable is allocated in `fpAllocateContext()`. This structure must be immediately `memset()` to zero. This sets all `BOOL` values to **`FALSE`**, all pointers to **`NULL`**, and all integers to **`0`**. Only non-zero, non-`NULL` and `BOOL`s that must be **`TRUE`** need to be initialized. This is best done in `fpInitDoc()`.
- Know where you are in the input source file.

  If you are processing headers, footers, notes, or (in the case of `rtfsr`) tables, you must be able to reposition the file pointer as required.
- Check buffer boundaries continuously.

  Whenever you advance through the buffer, you need to know whether there is enough of the input stream to completely process the current command. If not, you need to append the next section of the input file before continuing.
- Strive for a "clean" token stream.

  Use `filtertest` with the `-d` command-line option to generate a *token* version of the document. If there are redundant tokens, the reader is producing an inefficient token stream. You can keep the token stream free from redundancies by storing the state of the document and then applying the changes only when content is encountered. Content can be text, tabs, or picture objects. The `filtertest.exe` is in the directory *`install`*`\samples\utf8\bin`, where *`install`* is the path name of the Filter installation directory.
- Avoid large `switch()` statements whenever possible. They make both development and debugging more complicated than necessary. If there is a fixed set of commands, consider using a hash table that enables you to quickly identify a pointer to the function that handles that command.
- Filtering document metadata is a separate process.

  Remember that `fpGetSummaryInfo()` is a completely separate process from the rest of your code. It creates its own context variable structure. It does not have to call `fpFillBuffer()`.
- Use caution when processing headers, footers, and notes.

  If you need to process these items, the structured access layer calls `fpOpenStream()` and `fpCloseStream()`. It is critical that you save the state of your document and the file pointer position prior to returning from `fpOpenStream()`. Prior to returning from `fpCloseStream()`, you must restore the file pointer and the previous state of your document.
- Test your code.

  The structured access layer for each SDK is unique. Test your code in Filter SDK, Export SDK, and Viewing SDK.

Functions

This section describes the functions used by custom readers to manage the source file and generate token streams required to convert a document.

xxxsrAutoDet()

This function analyzes the source document and determines whether the detected file format requires the custom reader. It is called only when the `[CustomFilters]` section of the `formats.ini` file contains an entry identifying the complete file name of the custom reader. For more information on the `formats.ini` file, see File Format Detection, on page 166.

Syntax

```
Bool pascal _export xxxsrAutoDet(
    adTPDocInfo    *pTPDocInfo,
    KPTPIOobj      *pIO)
```

Arguments

`pTPDocInfo`	A pointer to the `adTPDocInfo` structure provided by the structured access layer.
`pIO`	A pointer to the I/O stream object for the document processed.

Returns

- `TRUE` if the file format matches that of the custom reader.
- `FALSE` if the file format does not match that of the custom reader.

Discussion

- Typically, only the first 1 KB of the file is read into a buffer and analyzed to determine if it matches the file format of the custom reader. If a match is determined, the following four members of the `adTPDocInfo` structure must be assigned before returning `TRUE`:

`adClass`	Must be set to `1`.
`adFormat`	A numerical value assigned to this reader in the `[Formats]` section of the `formats.ini` file.
`descStr`	A string describing the file format.
`mMnmemStr`	The initial part of the custom reader file name with the "`sr`" excluded.

- If the return value is `TRUE`, the custom reader is used to parse the file and generate the token stream.
- If the return value is `FALSE`, all other readers in the `[CustomFilters]` section of the `formats.ini` file are tried. If no match is found, the file detection process continues checking for the formats supported by Filter SDK.
- The entry in the `[Formats]` section of the `formats.ini` file should be of the form `aaa.bbb.ccc.ddd`, where `aaa` is the value used for the `adFormat` parameter, `bbb` is the value of the file class, `ccc` is the value of the minor format, and `ddd` is the value of the major version.

xxxAllocateContext()

This function allocates a global memory block for a data context. A handle to this memory is returned to the structured access layer. The structured access layer passes this handle back to all reader entry points.

Syntax

```
void * pascal _export xxxAllocateContext(
    void                    *pSALContext,
    LPARAM (pascal *fp)(void *,
    UINT                     LPARAM),
    Bool                    *pbOpenDoc,
    TPVAPIServices          *pVapi,
    DWORD                    dwFlags)
```

Arguments

`pSALContext`	A pointer to the global data context structure of the structured access layer.
`fp`	A pointer to a structure of callback functions supported by the structured access layer.
`pbOpenDoc`	You must set this `BOOL` value to **`TRUE`** if the allocation of memory for the global data context structure is successful.
`pVapi`	A pointer to a structure providing memory management and character conversion functions. Because this functionality is proprietary to HPE, `TPVAPIServices` is redefined as `void` in `kvcfsr.h`.
`dwFlags`	Run-time flags controlled by the structured access layer.

Returns

- Upon success, a pointer to the global data context structure for the custom reader. This pointer is passed back to all other custom reader entry points.
- Upon error, a `NULL` pointer. This causes the structured access layer to shut down the process.

Discussion

The global context structure should be `memset()` to zero in this function.

xxxFreeContext()

This function terminates an instance of the custom reader.

Syntax

```
int pascal _export xxxFreeContext(void *pCFContext)
```

Arguments

`pCFContext`	A pointer to the global context structure for the custom reader.

Returns

- Upon success, `KVERR_Success`.
- Upon error, a non-zero error code.

Discussion

All memory that still remains allocated within the custom reader must be freed within this function.

xxxInitDoc()

This function initializes non-zero, non-null members of `pContext`.

Syntax

```
int pascal _export xxxInitDoc(
    void             *pCFContext,
    adDocDesc        *pAutoInfo,
    long              lcbFileSize,
    KPTPIOobj        *pIO  )
```

Arguments

`pCFContext`	A pointer to the global context structure for the custom reader.
`pAutoInfo`	A pointer to an `adDocDesc` structure defined in `kwautdef`.
`lcbFileSize`	The length of the source file in bytes.

pIo	A pointer to a KPTPIOobj structure defined in kvioobj.h.

Returns

- Upon success, KVERR_Success.
- Upon error, a non-zero error code. This causes the structured access layer to shut down the process.

Discussion

- For custom readers, the pAutoInfo variable can be ignored.
- If the structured access layer has determined the length of the source file, that value is provided by the lcbFileSize parameter. If it is zero, the file size must be determined in this function.
- The pointer pIO provides access to file management functions defined in kvioobj.h.
- In this function, all non-zero, non-NULL members of the global context structure should be initialized.

xxxFillBuffer()

This function controls parsing of the source file and generation of tokens defined in kvtoken.h.

Syntax

```
int  pascal _export xxxFillBuffer(
    void    *pCFContext,
    BYTE    *pcBuf,
    UINT    *pnBufOut,
    int     *pnPercentDone,
    UINT     cbBufOutMax)
```

Arguments

pCFContext	A pointer to the global context structure for the custom reader.
pcBuf	A pointer to a memory buffer to which the tokens are written.
pnBufOut	A pointer to a variable that specifies the actual number of bytes written to the token buffer.
pnPercentDone	A pointer to a variable that specifies the percentage completed of the file parsing.
cbBufOutMax	A pointer to a variable that specifies the maximum number of bytes written to the token buffer.

Returns

- Upon success, `KVERR_Success`.
- Upon error, a non-zero error code. This causes the structured access layer to shut down the process.

Discussion

- Calls are made to read and parse the source file within this function.
- This function is called repeatedly by the structured access layer until either the return value is `FALSE` or the percentage complete is 100.
- The actual number of bytes written to the token buffer must not exceed the value of `cbBufOutMax`.

xxxGetSummaryInfo()

This function is required to extract document summary information.

Syntax

```
int  pascal _export xxxGetSummaryInfo(
    void                *pCFContext,
    KVSummaryInfoEx     *pInfo,
    BOOL                 bFreeInfo)
```

Arguments

`pCFContext`	A pointer to the global context structure for the custom reader.
`pInfo`	A pointer to a `KVSummaryInfoEx` structure defined in `kvtypes.h`.
`bFreeInfo`	A `BOOL` value indicating whether to free memory allocated for summary information.

Returns

- Upon success, `KVERR_Success`.
- Upon error, a non-zero error code.

Discussion

This function uses an instance of the global context structure that is different from the one used by all other reader interface functions.

This function can call the same functions used by `xxxFillBuffer()` or can be completely independent.

For more information, see Extract Metadata, on page 58.

xxxOpenStream()

This function is required when initiating processing of peripheral elements such as document headers, footers, footnotes, and endnotes.

Syntax

```
int pascal _export xxxOpenStream(
    void    *pCFContext,
    int      type,
    int      nOrdinal)
```

Arguments

`pCFContext`	A pointer to the global context structure for the custom reader.
`type`	An integer identifying a specific header, footer, footnote, or endnote. Options are defined in `kvcfsr.h`.
`nOrdinal`	An integer identifying a specific header, footer, footnote, or endnote. See the associated macros in `kvtoken.h`.

Returns

- Upon success, `KVERR_Success`.
- Upon error, a non-zero error code.

Discussion

A call to this function results in a call to `xxxFillBuffer()`. The function `xxxFillBuffer()` provides a new empty output buffer and a new token stream input buffer to process the alternate stream for peripheral elements. In this alternate stream, paragraph and character style properties are likely different from the main body. Therefore, as the document is parsed, the existing values from the main body must be saved. When the processing of the alternate stream is completed and processing of the main body resumes, these values must be restored in `xxxCloseStream()`.

xxxCloseStream()

This function is required when terminating processing for document headers, footers, footnotes, and endnotes.

Syntax

```
int pascal _export xxxCloseStream(
    void    *pCFContext,
```

```
    int      type)
```

Arguments

pCFContext	A pointer to the global context structure for the custom reader.
type	An integer identifying a specific header, footer, footnote, or endnote. Options are defined in kvcfsr.h.

Returns

- Upon success, KVERR_Success.
- Upon error, a non-zero error code.

Discussion

Prior to exiting this function, the previously saved values in the global context structure must be restored. This ensures that processing of the main body resumes with the correct document state.

xxxCharSet()

This function identifies the character encoding used within the source document.

Syntax

```
KVCharSet pascal _export xxxCharSet(
    void    *pCFContext,
    BOOL    *bMSBLSB)
```

Arguments

pCFContext	A pointer to the global context structure for the custom reader.
bMSBLSB	The BOOL value required for Unicode text. Set this argument to **TRUE** for Big Endian and **FALSE** for Little Endian.

Returns

One of the enumerated values defined in the KVCharSet structure of kvtypes.h.

Discussion

If the custom reader can determine the character encoding of the document, the corresponding enumerated value is returned. If the character encoding cannot be determined, KVCS_UNKNOWN is returned.

Appendix H: Password Protected Files

This section lists supported password-protected container and non-container files and describes how to open them.

Supported Password Protected File Types

The following table lists the password-protected file types that KeyView supports.

Key to support table

Symbol	Description
Y	Format is supported.
N	Format is not supported.
S	Support for viewing subfiles.
V	Support for viewing content.
P	Password required.
C	Password and certificate or User ID file required.

Supported password-protected file types

File Type	Version	Filter	Export	Extract	View	Credentials
PST (Windows)	n/a	N	N	Y	S	P
PST (non-Windows)[1]	n/a	N	N	Y	S	N
ZIP	n/a	N	N	Y	S	P
7-Zip	n/a	N	N	Y	S	P
RAR	n/a	N	N	Y	S	P
SMIME in MSG, EML, MBX	n/a	N	N	Y	N	C
Lotus Notes NSF	n/a	N	N	Y	N	C

[1] The native PST reader, `pstnsr`, does not require credentials to open password-protected PST files that use compressible encryption.

Supported password-protected file types, continued

File Type	Version	Filter	Export	Extract	View	Credentials
Adobe PDF	n/a	Y	Y	Y	V	P
Microsoft Office	97-2003 2007 2010	Y	Y	Y	V	P

Open Password Protected Container Files

This section describes how to extract password-protected container files by using the .NET API. The following guidelines apply to specific file types.

- **Lotus Notes NSF files**. If you are running a Notes client with an active user connected to a Domino server, you must specify the user's password as a credential regardless of whether the NSF files you are opening are protected. This enables KeyView to access the Notes client and the Lotus Notes API. If the Notes client is not running with an active user, KeyView does not require credentials to access the client.
- **PST files**.To open password-protected PST files that use high encryption (Microsoft Outlook 2003 only), you must use the MAPI-based PST reader (`pstsr`). The native PST reader (`pstnsr`) returns the error message `KVERR_PasswordProtected` if a PST is encrypted with high encryption.

To open container files

- Set the credential information to an `ExtractOpenDocConfig` object, and pass it to the `ExtractOpenDocument` method. For example:

```
odconfig = new ExtractOpenDocConfig();
odconfig.Password = m_password;
extContextID = m_objFilter.ExtractOpenDocument(inFile, odconfig);
```

Filter Password Protected Files

This section describes how to filter password-protected non-container files with the .NET API.

To filter password-protected files

- Use the `Password` property of the `Filter` class. Use the default `Filter()` constructor. For example:

```
objFilter = new Filter();
objFilter.Password = pwd;
```

  where `pwd` is a password of 255 or fewer characters.

Send documentation feedback

If you have comments about this document, you can contact the documentation team by email. If an email client is configured on this system, click the link above and an email window opens with the following information in the subject line:

Feedback on Filter SDK .NET Programming Guide (KeyView 11.5)

Add your feedback to the email and click **Send**.
