Introduction to VisiBroker

VisiBroker is a set of services and tools that enables you to build, deploy, and manage distributed enterprise applications in your corporate environment.

Accessing VisiBroker help topics

In the standalone Help Viewer

To access the online help through the standalone Help Viewer on a machine where the product is installed, use one of the following methods:

Windows

- Click Start > Programs > VisiBroker > Help Topics
- or
- Open the Command Prompt and go to the product installation `\bin` directory, then type:
`help`

UNIX

Open a command shell and go to the product installation `/bin` directory, then type:

```
help
```

Tip

During installation on UNIX systems, the default is to not include an entry for `bin` in your `PATH`. If you did not choose the custom install option and modify the default for `PATH` entry, and you do not have an entry for current directory in your `PATH`, use `./help` to start the help viewer.

From within a GUI tool

To access the online help from within a VisiBroker GUI tool, choose Help > Help Topics.

The Help menu also contains shortcuts to specific documents within the online help. When you select one of these shortcuts, the Help Topics viewer is launched and the item selected from the Help menu is displayed.

Documentation conventions

The documentation for VisiBroker uses the typefaces and symbols described below to indicate special text:

Convention	Used for
<i>italics</i>	Used for new terms and book titles.
<code>computer</code>	Information that the user or application provides, sample command lines and code.

Convention	Used for
bold computer	In text, bold indicates information the user types in. In code samples, bold highlights important statements.
[]	Optional items.
...	Previous argument that can be repeated.
>	Two mutually exclusive choices.

Platform conventions

The VisiBroker documentation uses the following symbols to indicate platform-specific information:

Windows: All supported Windows platforms.

Win2003: Windows 2003 only

WinXP: Windows XP only

Win2000: Windows 2000 only

UNIX: UNIX platforms

Solaris: Solaris only

Linux: Linux only

Contacting Micro Focus

Our Web site gives up-to-date details of contact numbers and addresses.

Further Information and Product Support

Additional technical information or advice is available from several sources.

The product support pages contain a considerable amount of additional information, such as:

- The WebSync service, where you can download fixes and documentation updates.
- The Knowledge Base, a large collection of product tips and workarounds.
- Examples and Utilities, including demos and additional product documentation.

To connect, enter <http://www.microfocus.com> in your browser to go to the Micro Focus home page.

Note:

Some information may be available only to customers who have maintenance agreements.

If you obtained this product directly from Micro Focus, contact us as described on the Micro Focus Web site, <http://www.microfocus.com>. If you obtained the product from another source, such as an authorized distributor, contact them for help first. If they are unable to help, contact us.

Information We Need

However you contact us, please try to include the information below, if you have it. The more information you can give, the better Micro Focus SupportLine can help you. But if you don't know all the answers, or you think some are irrelevant to your problem, please give whatever information you have.

- The name and version number of all products that you think might be causing a problem.
- Your computer make and model.
- Your operating system version number and details of any networking software you are using.
- The amount of memory in your computer.
- The relevant page reference or section in the documentation.
- Your serial number. To find out these numbers, look in the subject line and body of your Electronic Product Delivery Notice email that you received from Micro Focus.

Contact information

Our Web site gives up-to-date details of contact numbers and addresses.

Additional technical information or advice is available from several sources.

The product support pages contain considerable additional information, including the WebSync service, where you can download fixes and documentation updates. To connect, enter <http://www.microfocus.com> in your browser to go to the Micro Focus home page.

If you are a Micro Focus SupportLine customer, please see your SupportLine Handbook for contact information. You can download it from our Web site or order it in printed form from your sales representative. Support from Micro Focus may be available only to customers who have maintenance agreements.

You may want to check these URLs in particular:

Using the VisiTime Service

This section describes the VisiTime Service, a complete implementation of the OMG Time Service Specification, Version 1.1. The OMG Time Service specification defines two types of service which are implemented in VisiBroker:

- **Basic Time Service:** provides an interface to create objects representing time (a time stamp, for example) and intervals of time.
- **Timer Event Service:** provides an interface to manage Timer Event Handler objects. These objects are used to generate time based events based on user defined time settings.

Time Service overview

According to the OMG Time Service Specification, the OMG Time Service was created to allow a user to obtain the current time as well as an error estimate associated with it. Additionally, the Time Service was to provide a means of tracking events by ascertaining the order in which events occur, generate time-based event triggers or “alarms”, and compute the interval between two events.

How the Time Service defines time

The OMG Time Service Specification defines time using the Universal Time Coordinated (UTC) representation. The UTC representation uses hundreds of nanoseconds (10^{-7} seconds) as its basic unit of time, with its base time set at 15 October 1582 00:00:00 GMT. A range of approximately 30,000 years A.D. is supported by the UTC representation.

Similarly, the UTC representation defines a intervals of time or “relative time”. Like regular time, the basic unit of a relative time is 10^{-7} seconds. Ranges can span approximately plus-or-minus 30,000 years.

The Time Service relies on the presence of an underlying time source that provides the time and performs any necessary time synchronization. If the underlying time source meets the security criteria set out in Appendix A of the OMG Time Service Specification, then the Time Service is able to provide secure time as well.

Time Service components

The Time Service defines two types of CORBA objects that can be used by applications. These objects are the Universal Time Object (UTO), and the Time Interval Object (TIO). Using these two objects, a CORBA Time Service must provide for the ability to:

- Get the current time with associated inaccuracy in a UTO object via the `universal_time` operation.
- Get the current time and associated inaccuracy in a UTO object if the criteria for a secure time source can be met via the `secure_universal_time` operation.
- Create a UTO object to represent arbitrary time called a `new_universal_time` object.
- Create a UTO object from `UtcT` structure, via the `uto_from_utc` operation.
- Create a TIO from the `new_interval` operation.

Universal Time Object

The UTO interface corresponds to an object that contains UTC time and provides means to manipulate time in that object. UTO is an immutable object; it does not allow modifying the value of time contained in it. A UTO also provides for operations to be performed on basic time, such as comparing UTOs, comparing a UTO to a TIO interval, and getting the constituent parts of the UTO object.

Time Interval Object

Like a UTO, a TIO is an immutable object that represents a time interval and provides operations on time intervals. Methods are provided to get the interval value stored in the TIO object, determine overlapping between a TIO and one or more UTOs, and convert a TIO into a UTO.

Time Service services

In addition to providing time objects that can be manipulated and used by applications, the Time Service specifies a Timer Event Service and a Secure Time Service. The Timer Event Service provides a means for timer alarms to trigger events, which can be responded to using callback objects. The Secure Time Service allows only specified users of the system to set the time and/or specify the source of time.

Timer Event Service

The Timer Event Service provides a mechanism by which you can receive notifications when an event gets triggered. In other words, Timer Event Service provides a kind of alarm service. Your programs can register a `CosEventComm : PushConsumer` callback object with the Timer Event Service and obtain a special event handler object that provides operations to set and cancel alarms. When an alarm goes off, the Timer Event Service sends a notification to the callback object.

A Timer Event Handler object holds information about an event that is to be triggered at a specific time and the action to be taken when the event is triggered. The action taken is basically a call on the `push` method on the `CosEventComm : PushConsumer` object registered as the event handler. This method takes a `CORBA : Any` which contains the data to be pushed (the data is also specified when the event handler is registered with the event service).

The following operations are provided by the Timer Event Handler interface:

- Querying whether an event has been triggered with the `time_set` method.
- Querying the status of the Timer Event Handler with the `status` method.
- Setting the time for an event to trigger an alarm with the `set_timer` method.
- Canceling a trigger that has yet to go off with the `cancel_timer` method.
- Setting the data to be pushed when the event is triggered with the `set_data` method.

Alarms can be set using absolute or relative time definitions. They can also be set to occur periodically. The Timer Event Service interface provides operations for the complete lifecycle for the Timer Event Handler. The following operations are provided by the Timer Event Service interface:

- Registering an event handler and specify the callback object and the event data with the `register` method.
- Un-registering a previously registered event handler with the `unregister` method.
- Getting the time at which an event was triggered with the `event_time` method.

Secure Time Service

Only administrators authorized by the system security policy may set the time and specify the source of time. Once this is guaranteed the administrator can configure the Time Service to return secured time. With this in place it can be safely assumed that the underlying time source is secured and calling a `secure_universal_time` operation on the Time Service interface will return a secured time. If the underlying time source is not secured, a `CosTime::TimeUnavailable` exception will be raised upon invocation of the `secure_universal_time` operation on the Time Service interface.

VisiTime Service

The VisiTime Service is a factory for creating Universal Time Objects and Time Interval Objects.

Starting the VisiTime Service

The VisiTime Service can be started by using the `timeserv` launcher located in the `bin` directory of your VisiBroker installation. Running this command starts both the VisiTime Service and [“Timer Event Service” on page 6](#). The command syntax is:

Unix

```
timeserv [driver_options] [timeserv_options] &
```

Windows

```
timeserv [driver_options] [timeserv_options]
```

You can also start the Time Service using the VBJ launcher:

```
vbj [driver_options]
com.borland.vbroker.CosTime.TimeServer
```

The following driver options are available:

Option	Description
-install <service-name>	(Windows only) Install as a Windows service using the name provided. This option cannot be used when starting the Time Service using <code>vbj</code> .
-remove <service-name>	(Windows only) Uninstall this service. This option cannot be used when starting the VisiTime Service using <code>vbj</code> .

The general driver options are also available for both UNIX and Windows. See the *VisiBroker for C++ Developer's Guide* or *VisiBroker for Java Developer's Guide* for more information.

The following VisiTime Service options are available:

Option	Description
-?, -h, -help, -usage	Print usage information.
-props <properties-file>	Use the supplied properties file as the configuration file when starting up the VisiTime Service. Note that a property defined in this file will get overridden if the same property is also passed on the command line.

Starting Secure VisiTime Service

When the underlying time source is secure and follows the guidelines given in Appendix A of the OMG Time Service specification, then the VisiTime Service can be started as a secure Time Service. Calls to `TimeService::secure_universal_time` would succeed in this case. Note that here security only refers to the security of the underlying time source. To start a secured VisiTime Service:

Unix

```
timeserv -J-Dvbroker.time.source.secured=true &
```

Windows

```
start timeserv -J-Dvbroker.time.source.secured=true
```

Bootstrapping the VisiTime Service

There are three ways to start a client application to get the initial reference to the VisiTime Service. These are:

- Using the `ORBInitRef` command-line option.
- Using the `ORBDefaultInitRef` command-line option.
- Using the Smart Agent.

When using either of the command-line options, client applications can make use of the ORB's `resolve_initial_references` method to obtain the Time Service or the Timer Event Service. For example:

C++

```

...
CORBA::ORB_var orb = CORBA::ORB_init (argc, argv);

// Get reference to Time Service
CORBA::Object_var obj_t = orb-
>resolve_initial_references("CosTimeService");
CosTime::TimeService_var time_svc =
CosTime::TimeService::_narrow (obj_t.in());

// Get reference to Timer Event Service
CORBA::Object_var obj_te = orb-
>resolve_initial_references("CosTimerEventService");
CosTimerEvent::TimerEventService_var timer_svc =

CosTimerEvent::TimerEventService::_narrow (obj_te.in());
...

```

Java

```

// Get reference to Time Service
org.omg.CosTime.TimeService timeSvc =
org.omg.CosTime.TimeServiceHelper.narrow(

orb.resolve_initial_references("CosTimeService"));

// Get reference to Timer Event Service
org.omg.CosTimerEvent.TimerEventService timerSvc =
org.omg.CosTimerEvent.TimerEventServiceHelper.narrow(

orb.resolve_initial_references("CosTimerEventService"));
...

```

Bootstrapping using ORBInitRef

The most common usage scenario for ORBInitRef is to use a corbaloc URL to specify the initial reference. Other URL schemes are also possible. For example, using the IOR string or the file URL (Java only) to specify the name of the file containing Time Service IOR. The following commands bootstrap the Time Service and Timer Event Service running on port 5566 to the client application:

C++

```

<client_application> -ORBInitRef
CosTimeService=corbaloc::<host>:5566/CosTimeService

<client_application> -ORBInitRef
CosTimerEventService=corbaloc::<host>:5566/
CosTimerEventService

```

Java

```

vbj <client_application> -ORBInitRef
CosTimeService=corbaloc::<host>:5566/CosTimeService

vbj <client_application> -ORBInitRef
CosTimerEventService=corbaloc::<host>:5566/
CosTimerEventService

```

Bootstrapping Using ORBDefaultInitRef

Like `ORBInitRef`, `ORBDefaultInitRef` commonly uses `corbaloc` URLs to specify initial references. Other URL schemes are valid as well, depending on your implementation. The following command bootstraps both the Time Service and the Timer Event Service to the client application, using `ORBDefaultInitRef`:

C++

```
<client_application> -ORBDefaultInitRef corbaloc::<host>:5566
```

Java

```
vbj <client_application> -ORBDefaultInitRef corbaloc::<host>:5566
```

You can also specify the `ORBDefaultInitRef` as a property with the `vbj` command starting the client application. The following command also bootstraps the Time Service, but specifies `ORBDefaultInitRef` as a property:

```
vbj -DORBDefaultInitRef=corbaloc::<host>:5566 <client_application>
```

Bootstrapping Using the SmartAgent

Client applications can also make use of the `VisiBroker` `bind` method to get the initial reference to the Time Service and the Timer Event Service from the `SmartAgent`. In Java the `TimeServiceHelper` and `TimerEventServiceHelper` classes are used to perform the bind. When executing the method, you specify the name of the Time Service and Timer Event Service to which you're connecting (and in Java, the ORB hosting them). For example:

C++

```
CORBA::ORB_var orb = CORBA::ORB_init (argc, argv);

// Get reference to Time Service
CosTime::TimeService_var time_svc =
CosTime::TimeService::_bind("VBTimeService");

// Get reference to Timer Event Service
CosTimerEvent::TimerEventService_var timer_svc =
CosTimerEvent::TimerEventService::_bind
("VBTimerEventService");
```

Java

```
org.omg.CORBA.ORB orb = org.omg.CORBA.ORB.init(args,null);

// Get reference to Time Service
org.omg.CosTime.TimeService timeSvc =
org.omg.CosTime.TimeServiceHelper.bind(orb,
"VBTimeService");

// Get reference to Timer Event Service
org.omg.CosTimerEvent.TimerEventService timerSvc =
org.omg.CosTimerEvent.TimerEventServiceHelper.bind(orb,
"VBTimerEventService");
```

Running the Time Service in-process

The VisiTime service has the ability to run in-process or co-located with Java applications. You need not make any application code changes when switching from out-of-process to in-process mode. Enabling the in-process Time Service is controlled through the VisiBroker property `vbroker.time.enableInProc`.

Regardless of whether the Time Service is using in-process or out-of-process execution mode, user applications will use `orb.resolve_initial_references("CosTimeService")` and `orb.resolve_initial_references("CosTimerEventService")` to obtain initial references to the Time Service and Timer Event Service respectively. There would be a difference in the bootstrapping mechanism for in-process and remote Time Service respectively. User applications should not specify the `ORBInitRef` property with in-process Time Service. Instead, they must enable the VisiBroker property `vbroker.time.enableInProc=true`. If `ORBInitRef` is used together with `vbroker.time.enableInProc=true`, only `ORBInitRef` will take effect.

NTP server support for Time Source

By default, the VisiTime Service implementation uses the System Time as the Time Source. Alternatively it can be configured to use a NTP Server as a Time Source. This is controlled through the VisiBroker property `vbroker.time.ntp.addr`.

Specifying NTP server addresses and failover

The value for the `vbroker.time.ntp.addr` can be one or a sequence of comma-separated strings representing the NTP Server addresses. Both IPv4 and IPv6 format addresses can be specified as well. For example, consider three NTP server addresses given here:

```
vbroker.time.ntp.addr=foo.com, [fe220::103:baaa:fbbb:fedf] :
123,101.121.145.100:124
```

The first address, `foo.com`, relies on the internal DNS lookup. Since no port is specified, the default NTP port 123 is used. The second entry, `[fe220::103:baaa:fbbb:fedf] :123`, is an IPv6 format address enclosed in square brackets. Here, the port is defined specifically as 123. The final entry, `101.121.145.100:124` is the familiar IPv4 format, with the port number 124 specified as well.

The VisiTime Service will first try to contact the first NTP Server in the sequence. If the address is valid and the server is available, the time of the NTP Server will be returned to the caller. Assuming that the first server in the list was not available, the implementation will transparently fail over to the second in the list and so on until it retrieves the required time value from one of the Server in the list. If all of the Servers are unreachable, VisiTime Service will throw an exception to the caller. Depending on the method called, the exception can be either `CosTime::TimeUnavailable` or a CORBA system exception such as `COMM_FAILURE`.

Configuring the VisiTime Service

The VisiTime Service can be configured using the VisiBroker Console, using properties specified on the command line, or using properties specified in a properties file. The following properties are provided for the VisiTime Service.

Property	Default	Description
<code>vbroker.time.name</code>	(none)	Specifies a name for this Time Service. This name is used to identify a particular Time Service in the Console or through Server Manager.
<code>vbroker.time.listener.port</code>	0	The listener port for the Time Service. The default value of 0 means any random port will be picked. This property does not take effect if the listener port is set through the Server Manager's <code>vbroker.se.iiop_tp.scm.iiop_tp.listener.port</code> property.
<code>vbroker.time.timeRefFile</code>	(none)	Specifies the name of file where Time Service IOR is written. Not effective when the Time Service is run in in-process execution mode.
<code>vbroker.time.timerEventRefFile</code>	(none)	Specifies the name of file where the Timer Event Service IOR is written. This property is not effective for in-process Time Service.
<code>vbroker.time.enableInProc</code>	false	Java only. Run the Time Service as in-process. It should be specified on the Time Service client and not the Time Service itself.
<code>vbroker.time.leapSeconds</code>	0	Adds leap seconds to the time returned by the Time Source. A leap second is a second added to Coordinated Universal Time (UTC) to make it agree with astronomical time to within 0.9 second. Leap seconds have been added to UTC since 1972. The current value is 25 seconds (as of 30 June 2012). Use this property in cases when the time source attached to Time Service is not corrected for leap seconds.

Property	Default	Description
<code>vbroker.time.source.secured</code>	false	Tells the Time Service that the Time Source is a secured one. When this property is true, a call to <code>secure_universal_time</code> will always succeed. Otherwise, it throws the <code>TimeUnavailable</code> exception.

Property	Default	Description
<code>vbroker.time.threadMax</code>	0	Sets the maximum number of threads in the Timer Event Service thread pool.
<code>vbroker.time.threadMin</code>	5	Sets the minimum number of threads in the Timer Event Service thread pool.
<code>vbroker.time.threadMaxIdle</code>	100	Sets the time in seconds after which an idle thread will be removed from the pool. However, the number of threads in the pool will be kept to the value of <code>threadMin</code> .

Property	Default	Description
vbroker.time.logLevel	C++: 0 Java: emerg	Specifies the logging level of message that will be logged. When set to the default value the system logs messages when the system is unusable, or in a panic condition. Acceptable values are: <ul style="list-style-type: none"> emerg (0): indicates some panic condition. alert (1): a condition that requires user attention--for example, if security has been disabled. crit (2): critical conditions, such as a device error. err (3): error conditions. warning (4): warning conditions--these may accompany some troubleshooting advice. notice (5): conditions that are not errors but may require some attention, such as upon the opening of a connection. info (6): informational, such as binding in progress. debug (7): debug conditions understood by developers.
vbroker.time.logger.output	stdout	The name of the file where the logger output is written. Default is to print to screen.
vbroker.time.logger.appName	TimeService	The name of the application to appear in the log output.

Property	Default	Description
vbroker.time.ntp.addr	(none)	Specifies the NTP server's address and port. The value for this property is specified as follows: <pre>addr[:port>>[, addr[:port>>]</pre> Where <code>addr</code> is the host name such as <code>myhost.com</code> or an IP address. Both IPv4 and IPv6 addresses are supported. IPv6 addresses must be enclosed in square brackets. The port is optional. If not specified, the default Time Service port 123 is used. When multiple addresses are specified, then NTP server failover happens if communication with one of the servers fails. The Time Service will try all the servers before throwing a <code>TimeUnavailable</code> exception.
vbroker.time.ntp.timeout	5000	The time in milliseconds to wait for a reply from the NTP server. If multiple NTP servers are specified then failover to next server happens after the timeout expires.

Creating Time Service Objects with the TimeService interface

The VisiTime Service interface `TimeService` provides methods for creating UTOs and TIOs, but doesn't provide any methods to deactivate/destroy these Objects. VisiBroker's `TimeService` implementation uses the default servant-based dispatch mechanism limiting the number of these objects,

meaning that for any number of these references the real servant processing the request is only one. You will not, therefore, need to be concerned with a large number of Time Service objects--UTOs and TIOs--being created. You use the `TimeService` interface to create UTOs and TIOs. Before creating these objects, you must resolve to the Time Service and narrow it (using the `TimeServiceHelper` in Java). The following code samples explain how to do this:

C++

```
//Initialize the ORB
CORBA::ORB_var orb = CORBA::ORB_init(argc, argv);

//Resolve the TimeService interface
CORBA::Object_var obj_t = orb-
>resolve_initial_references("CosTimeService");

//Narrow the TimeService interface
CosTime::TimeService_var time_svc =
CosTime::TimeService::_narrow (obj_t.in());
```

Java

```
import org.omg.CORBA.ORB;
import org.omg.CosTime.*;
...
//Initialize the ORB
ORB orb = ORB.init(args, null);

//Resolve the TimeService interface
org.omg.CORBA.Object obj =
orb.resolve_initial_references("CosTimeService");

//Narrow it properly using the Helper
TimeService timeService = TimeServiceHelper.narrow(obj);
```

Once you have resolved to and narrowed the `TimeService` interface, you can use it to create UTOs and TIOs.

Creating UTOs using the TimeService interface

Use the `TimeService` method `universal_time()` to create a Universal Time Object containing the current time. For example,

C++

```
CosTime::UTO_var uto = time_svc-> universal_time();
```

Java

```
UTO uto = timeService.universal_time();
```

creates a Universal Time Object `uto` whose time value is the current time at the execution of the method.

You can also create a UTO containing a relative time of your choosing (not obtained using a Time Source) using the `new_universal_time` method. You provide three arguments to this method:

- the 64-bit time value. This is the number of hundreds of nanoseconds that have elapsed since base time and is a C++ `CORBA::ULongLong` or Java `long` data type.
- the time inaccuracy value.

- the time displacement factor value (in the form of minutes of displacement from the Greenwich Meridian), a C++ CORBA::Short or Java short data type.

For example:

C++

```
CosTime::UTO_var uto = time_svc->new_universal_time
    ((CORBA::ULongLong)10000000, 0, (CORBA::Short)0);
```

Java

```
UTO uto = timeService.new_universal_time
    (10000000L, 0, (short)0);
```

Creating TIOs using the TimeService interface

You can create TIOs using the TimeService interface. The new_interval method takes two arguments of type CORBA::ULongLong (C++) or long (Java), which are the bounds of the time interval expressed as hundreds of nanoseconds since base time. For example:

C++

```
//Create a TIO that represents a specific interval
CosTime::TIO_var tio =
    time_svc->new_interval((CORBA::ULongLong)10000000,
        (CORBA::ULongLong)20000000);
```

Java

```
//Create a TIO that represents a interval TIO tio
= _timeService.new_interval(10000000L, 20000000L);
```

Using the Timer Event Service

This section explains how to resolve to a Timer Event Service, obtain TimerEventHandlers, set alarms using the TimerEventHandlers, cancel an alarm that was previously set, and unregister a TimerEventHandler.

Before creating and utilizing TimerEventHandlers, you must resolve to the Timer Event Service itself, as well as the ORB's standard Event Service providing the PushConsumer object. For example:

C++

```
//Initialize the ORB
CORBA::ORB_var orb = CORBA::ORB_init(argc, argv);

//Resolve the TimerEventService
CORBA::Object_var obj_t = orb-
>resolve_initial_references("CosTimerEventService");
CosTime::TimerEventService_var time_evsvc =
CosTime::TimerEventService::_narrow(obj_t.in());

//Resolve to the EventService
CORBA::Object_var obj_ev = orb-
>resolve_initial_references("EventService");
CosEventChannelAdmin::EventChannel_var channel =
CosEventChannelAdmin::EventChannel::_narrow(obj_ev.in());
```

Java

```

import org.omg.CosTimerEvent.*;
import org.omg.TimeBase.*;
...

//Initialize the ORB
ORB orb = ORB.init(args, null);

//Resolve the TimerEventService
TimerEventService
timerEventService=TimerEventServiceHelper.narrow(
_orb.resolve_initial_references("CosTimerEventService"));

//Resolve to the EventService
EventChannel channel =
EventChannelHelper.narrow(_orb.resolve_initial_references(
"EventService"));

```

Creating TimerEventHandlers

The Timer Event Service provides an operation to register a `CosEventComm::PushConsumer` together with a `CORBA::Any` that provides event data. Internally, an instance of `TimerEventHandler` is created, with which the event data and `PushConsumer` are associated. You can at any point change the event data, but the `PushConsumer` is immutably associated with the `TimerEventHandler` and cannot be changed.

Once you have resolved the Timer Event Service and Event Service, and you have obtained a channel from the latter, you can create the Event Handler implementation. To do so, you must follow these six steps:

- 1 Create a `ProxyPushSupplier` object to push the event data to the consumer.
- 2 Create a `PushConsumer` object to receive the event data.
- 3 Associate the `ProxyPushSupplier` with its `PushConsumer`.
- 4 Obtain a `ProxyPushConsumer` object from the event channel. This is the object that will be registered with the Timer Event Service.
- 5 Create the event data with a new `CORBA::Any`.
- 6 Create the event handler by executing the Timer Event Service's `register` method, using the `ProxyPushConsumer` and the `CORBA::Any` objects as arguments.

The following tables show source code used to execute each of the steps above:

C++

Step	Code
1	<pre>//Create a ProxyPushSupplier CosEventChannelAdmin::ConsumerAdmin_var cns_adm = channel->for_consumers(); CosEventChannelAdmin::ProxyPushSupplier_var pushSupplier = cns_adm->obtain_push_supplier();</pre>
2	<pre>//Create the PushConsumer, PushView here is the implementation of // PushConsumer PushView* view = new PushView();</pre>
3	<pre>//Connect the PushConsumer pushSupplier->connect_push_consumer(view->_this());</pre>
4	<pre>//Get a ProxyPushConsumer from the Event Channel CosEventChannelAdmin::SupplierAdmin_var sup_adm = channel->for_suppliers(); CosEventChannelAdmin::ProxyPushConsumer_var proxy = sup_adm->obtain_push_consumer();</pre>
5	<pre>//Create the data that we want to receive when the event is // triggered CORBA::Any any ; any <<="my data";</pre>
6	<pre>//Register the PushConsumer and the event data to obtain a // TimerEventHandler CosTimerEvent::TimerEventHandler_var eventHandler = time_evsvc->register(proxy,any);</pre>

Java

Step	Code
1	<pre>//Create a ProxyPushSupplier ProxyPushSupplier pushSupplier = channel.for_consumers().obtain_push_supplier();</pre>
2	<pre>//Create the PushConsumer, PushView here is the implementation of // PushConsumer PushView view = new PushView();</pre>
3	<pre>//Connect the PushConsumer pushSupplier.connect_push_consumer(view._this(orb));</pre>
4	<pre>//Get a ProxyPushConsumer from the Event Channel ProxyPushConsumer proxy = channel.for_suppliers().obtain_push_consumer();</pre>
5	<pre>//Create the data that we want to receive when event is triggered Any any = orb.create_any(); Any.insert_string("my data");</pre>
6	<pre>//Register the PushConsumer and the event data to obtain a // TimerEventHandler TimerEventHandler eventHandler = timerEventService.register(proxy,any);</pre>

Setting Alarms for TimerEventHandlers

In order to use your newly-created `TimerEventHandler`, you set alarms using the `EventTimer` interface. The `set_timer` method is used to set an alarm. It takes two arguments: the type of alarm and a UTO object. Three types of alarms are available:

- `TTAbsolute`: the alarm is triggered at an absolute time specified by the UTO.
- `TTRelative`: the alarm is triggered at the UTO relative to the current time (the UTO represents time from the current absolute time, not the time base).
- `TTPeriodic`: the alarm occurs periodically, repeating at each relative time specified by the UTO.

To set an alarm, you must:

- 1 Create a `TimerEventHandlers` object (see [“Creating TimerEventHandlers”](#)).
- 2 Create a new UTO that will be used to trigger the alarm.
- 3 Use the Event Handler's `set_timer` method to set the alarm.

For example, the following code sets an alarm for a `TimerEventHandler` object called `eventHandler`:

C++

```
//Create an UTO that represents relative time
CosTime::UTO_var uto = time_svc->new_universal_time
    ((CORBA::ULongLong)10000000,0,(CORBA::Short)0);

//set a periodic timer on the TimerEventHandler, this
// alarm would trigger after every 1 second
// (10000000/10000) second has elapsed and the event data
// will be pushed to the PushConsumer that was previously
// registered
eventHandler->set_timer(CosTimerEvent::TTPeriodic,uto);
```

Java

```
//Create an UTO that represents a relative time
UTO uto = timeService.new_universal_time
    (10000000L,0,(short)0);

//set a periodic timer on the TimerEventHandler, this
// alarm would trigger after every 1 second
// (10000000/10000) second has elapsed and the event data
// will be pushed to the PushConsumer that was previously
// registered
eventHandler.set_timer(TimeType.TTPeriodic,uto);
```

Note

The Timer Event Service minimum relative interval for which an alarm can be set is 1 millisecond. Any value less than 1 millisecond will be transparently converted to 1 ms.

Canceling a timer and unregistering a TimerEventHandler

To cancel an event handler's timer, simply execute the handler's `cancel_timer` method:

C++

```
eventHandler->cancel_timer();
```

Java

```
eventHandler.cancel_timer();
```

To unregister an event handler entirely, call the event service's `unregister` method:

C++

```
eventService->unregister(eventHandler);
```

Java

```
eventService.unregister(eventHandler);
```

Friendly Time Object

This is an object with a friendly interface to convert the 64-bit time representation to human readable components like year, month, day etc and vice versa: the `TimeI` object. The `TimeI` object can be viewed as a representation conversion object. The general technique for using it is to create one using the operation `FriendlyTime::TimeService::time()`. This creates a `TimeI` object with time set to zero in it. Then the `_set` operations can be used to set the values of the various attributes. Finally, the attribute `time` can be used to get the corresponding `TimeT` value.

Conversely, one can set any `TimeT` value in the `time` attribute and then get the year, month, and so forth. from the appropriate attributes.

The IDL for the friendly time object is as follows:

```
module FriendlyTime {
  interface TimeI {
    attribute YearT year;
    attribute MonthT month;
    attribute DayT day;
    attribute HourT hour;
    attribute MinuteT minute;
    attribute SecondT second;
    attribute MicrosecondT microsecond;
    attribute TimeBase::TimeT time;
    void reset(); // set all attributes to zero
  };
};
```

The following code sample illustrates the usage of the friendly time object:

C++

```
//Initialize the ORB
CORBA::ORB_var orb = CORBA::ORB_init(argc, argv);

//Resolve the FriendlyTimeService
CORBA::Object_var obj_t = orb->resolve_initial_references
    ("CosTimeService");
FriendlyTime::TimeService_var time_svc =
    FriendlyTime::TimeService::_narrow (obj_t.in());

//Get a TimeI object from the FriendlyTime
FriendlyTime::TimeI_var timeI = time_svc->time();

//Get the current time in a UTO
CosTime::UTO_var uto = time_svc-> universal_time();

//Set the current time in the TimeI object
timeI->time(uto->time());

//Get the various attributes from TimeI Object in a human
//readable format and print to the standard output
cout << " Year is :" << timeI->year() << endl;
cout << " Month is :" << timeI->month() << endl;
cout << " Day is :" << timeI->day() << endl;
cout << " Hour is :" << timeI->hour() << endl;
cout << " Minute is :" << timeI->minute() << endl;
cout << " Second is :" << timeI->second() << endl;
cout << " MicroSecond is :" << timeI->microsecond() <<
endl;
```

Java

```
import org.omg.CORBA.ORB;
import org.omg.CosTime.*;
...
//Initialize the ORB
ORB orb = ORB.init(args, null);

//Resolve the FriendlyTimeService
org.omg.FriendlyTime.TimeService friendlyTs =
    org.omg.FriendlyTime.TimeServiceHelper.narrow(
    _orb.resolve_initial_references("CosTimeService"));

//Get a TimeI object from the FriendlyTime
org.omg.FriendlyTime.TimeI timeI = friendlyTs.time();

//Get the current time in a UTO
UTO uto = friendlyTs.universal_time();

//Set the current time in the TimeI Object
timeI.time(uto.time());

//Get the various attributes from TimeI Object in a human
//readable format and print to //the standard output
System.out.println("Year is :"+ timeI.year());
System.out.println("Month is :"+ timeI.month());
```

```
System.out.println("Day is :"+ timeI.day());
System.out.println("Hour is :"+ timeI.hour());
System.out.println("Minute is :"+ timeI.minute());
System.out.println("Second is :"+ timeI.second());
System.out.println("MicroSecond is :"+
timeI.microsecond());
```
